    o Abrupt onset and offset of repetitive, rhythmic jerks of the eyelids with simultaneous upward deviation of the eyeballs and extension of the head
    o Typically occurs at 4 to 6 Hz
    o Lasts <6 seconds
    o Impairment of consciousness often incomplete with awareness mostly retained
    o Associated with epilepsy with eyelid myoclonus

EPIDEMIOLOGY
- Incidence: 6 to 8/100,000 per year
- Prevalence: 5 to 50/100,000
- Predominant age of onset: 1 to 8 years
- Predominant gender: female > male (2:1) with male predominance in myoclonic absence seizure

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Etiology is mainly genetic with complex, multifactorial inheritance; however, may be secondary to a variety of congenital or acquired brain disorders such as hypoxia–ischemia, trauma, CNS infection, cortical malformations, or inborn errors of metabolism.
- Absences are triggered in the thalamus when γ-aminobutyric acid (GABA)-mediated activity induces prolonged hyperpolarization and activates T-type (“low-threshold”) calcium channels, resulting in sustained-burst firing of these neurons causing absence seizures.

**Genetics**
- 70–85% concordance occurs in monozygotic twins; 82% share EEG features.
- 33% concordance among first-degree relatives
- 15–45% have a family history of epilepsy.
- Mutations of GABA-A/B receptors, calcium or chloride channels
- Mutations of SLC21A, which encodes GLUT1

**ALERT**
Onset of absence seizures <4 years, consider GLUT1 deficiency syndrome

**COMMONLY ASSOCIATED CONDITIONS**
- Difficulties in visual attention and visuospatial skills, verbal learning and memory, fine motor skills, executive functions, and reduced language abilities
- Elevated rates of behavioral and psychiatric comorbidities including ADHD, anxiety, depression, social isolation, and low self-esteem

**DIAGNOSIS**

**HISTORY**
- Detailed description of episode including activity at onset, any automatisms, duration of episode, frequency of episodes, aura or postictal state, age of onset, and birth and developmental history.
- Teachers report that child seems to daydream or zone out frequently.
- Child will forget portions of conversations.
- Child with normal IQ underperforms in school.

**ALERT**
Seizures are often so brief that untrained observers are not aware of the occurrence.

**PHYSICAL EXAM**
- Unless a child has another genetic or acquired abnormality, a neurologic exam usually is normal. Abnormal physical exam indicates the need for further diagnostic workup (e.g., MRI, metabolic, or genetic testing).
Seizures may be induced by hyperventilation:
- Have the child blow on a pinwheel or similar exercise for 3 to 5 minutes to provoke seizure.
- Alternatively, ask the patient to perform hyperventilation with eyes closed and count.
  Patient will open eyes at onset of seizure and stop counting.

**ALERT**
Absence seizures are not associated with sensitivity to light or other photic stimuli (e.g., strobe lights).

**DIFFERENTIAL DIAGNOSIS**
- JAE
- JME
- GLUT1 deficiency syndrome
- Complex partial seizures
- Psychogenic nonepileptic seizures
- ADHD
- Confusional states and acute memory disorders
- Migraine variants
- Panic/anxiety attacks
- Breath-holding spells
- Nonepileptic staring spells
- Febrile seizures
- Status epilepticus

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Video-EEG, including sleep and awake with hyperventilation resulting in spike-wave complexes from <2.5 to 6.0 Hz, depending on type of absence seizure, is standard for diagnosis (1)[B].
- Imaging is not routinely indicated in children with typical absence and normal neurologic exam and cognition. If imaging is performed, MRI is preferable to CT scan due to higher sensitivity for anatomic abnormalities (1)[B].
- Presently, no laboratory values can definitively prove or rule out the diagnosis of an absence seizure. However, labs such as electrolytes, creatinine, liver and renal function tests, TSH, CBC, and toxicology screen can rule out endocrine, metabolic, toxic, or infectious etiologies (2)[C].

**Follow-Up Tests & Special Considerations**
- Drug levels are useful in evaluating symptoms of toxicity or for breakthrough seizures.
- Follow blood chemistry, hepatic function, blood counts, etc., specific to drug regimen.

**TREATMENT**

**GENERAL MEASURES**

**ALERT**
Review seizure precautions with every patient diagnosed with or suspected to have epilepsy.
Seizure precautions are to prevent injury. Patients should refrain from activities that would put them at risk if a seizure occurred (e.g., climbing heights, swimming unsupervised, cycling on busy roads, driving). Providers should be familiar with state laws concerning driving with epilepsy.

**MEDICATION**

**ALER**

Certain common anticonvulsants may exacerbate absence including carbamazepine, oxcarbazepine, phenytoin, phenobarbital, tiagabine, vigabatrin, pregabalin, and gabapentin.

**First Line**
- Ethosuximide blocks T-type calcium channels:
  - First line, high efficacy (3)[A], fastest onset of efficacy (4)[B], and fewer adverse attentional effects compared to valproic acid (3)[A]; however, is only effective against absence seizures
  - Side effects: vomiting, diarrhea, abdominal discomfort, hiccups, headache, sedation
  - Adverse effects: aplastic anemia, skin reactions, and renal/hepatic impairment. Monitor CBC and CMP (5)[C].
- Valproic acid has multiple mechanisms:
  - Alternative first line
    - Very effective but has highest rate of adverse events leading to treatment discontinuation, including negative attentional effects and weight gain (3)[A]; is considered broad spectrum due to effective against absence and comorbid seizure types such as myoclonic, tonic–clonic, and partial
    - Side effects: tremor, drowsiness, dizziness, weight gain, alopecia, sedation, vomiting
    - Adverse effects: teratogenicity, behavior/cognitive abnormalities, hepatotoxicity, pancreatitis. Monitor CMP, amylase, and lipase (5)[C]; reduced bone mineral density and increased risk of osteoporosis and fractures

**Second Line**
Lamotrigine affects sodium channels:
- Controls seizures but may be less efficacious than ethosuximide or valproic acid (3)[A]
- Side effects: rash, diplopia, headache, insomnia, dizziness, nausea, vomiting, diarrhea
- Adverse effects: rare Stevens-Johnson rash, more often when coadministered with valproic acid

**ISSUES FOR REFERRAL**
Failure to gain seizure control for at least 1 year with two AEDs (whether as monotherapy or in combination) should prompt referral to neurologist for confirmation of the diagnosis for seizure and/or syndrome classification and, if appropriate, for consideration of epilepsy surgery (4)[B].

**Pediatric Considerations**
- Prescribe vitamin D supplementation (usual dose 400 to 1,000 IU/day) in children taking valproic acid due to AE of reduced bone mineral density (6)[A].
- Fatal hepatotoxicity with valproic acid risk is greatest in <2 years old (5)[C].

**Pregnancy Considerations**
Anticonvulsants, especially valproic acid, are associated with an increase in fetal malformations. Use of valproic acid in women of childbearing age, who are not using adequate birth control, is contraindicated.

ADDITIONAL THERAPIES
Vagal nerve stimulator (VNS) may be considered as an option for medically refractory absence epilepsy (7)[C].

SURGERY/OTHER PROCEDURES
Epilepsy surgery including ablation and resection for medically refractive absence epilepsy

COMPLEMENTARY & ALTERNATIVE MEDICINE
A ketogenic diet should be considered early if medication is ineffective (6)[A].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Absence epilepsy rarely requires admission.
- Status epilepticus requires inpatient management.
- Discharge criteria
  - Resolution of status epilepticus

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patients should be monitored periodically by a neurologist for evolution of absence epilepsy into other seizure types.

PROGNOSIS
- Patients whose shortest pretreatment EEG seizures are >20 seconds in duration are more likely to achieve seizure freedom, regardless of treatment.
- Typical absence seizures generally cease spontaneously by age 12 years or sooner.
- <10% develop generalized tonic–clonic seizures.
- Male sex and an early age at diagnosis are associated with the need for two medications to control the disease.

COMPLICATIONS
- Causes of seizure exacerbations: noncompliance with treatment, lack of sleep, drugs that lower seizure threshold (e.g., alcohol, cocaine, high-dose PCN, isoniazid overdose, neuroleptics, Wellbutrin)
- Reported frequencies of typical absence status epilepticus range from 5.8% to 9.4%.

CODES

ICD10
- G40.409 Other generalized epilepsy and epileptic syndromes, not intractable, without status
  epilepticus
- G40.419 Oth generalized epilepsy, intractable, w/o stat epi
- G40.401 Oth generalized epilepsy, not intractable, w stat epi

CLINICAL PEARLS
- Children with CAE can exhibit cognitive, behavioral, and psychosocial comorbidities. For
  these children, attentional deficits are the most important marker of cognitive dysfunction and
  often associated with reduced academic performance, anxiety, depression, and behavioral
  disorders.
- If parents are unable to determine the cause of a staring spell, try suggesting that parents
  mention something exciting or unexpected like “ice cream” during a spell to get the child’s
  attention rather than calling his or her name.
- Ethosuximide and valproic acid are first-line agents in treatment of absence seizures.
- Failure to gain seizure control for at least 1 year with two AEDs, consider referral to
  neurologist for confirmation of seizure disorder and/or additional/alternative therapies
  including ketogenic diet, VNS, and surgery.
- Review seizure precautions with every patient.
- Maintain a seizure diary to help identify type and cause of seizures
- Create a seizure response plan
  (https://www.epilepsy.com/sites/core/files/atoms/files/130SRP_MySeizureResponsePlan-
  fillable.pdf).
SEIZURE DISORDER, FOCAL
Charles J. McClure, DO ● Noel Dunn, MD

BASICS

DESCRIPTION
- Seizures occur when abnormal synchronous neuronal discharges in the brain cause transient cortical dysfunction.
- Generalized seizures involve bilateral cerebral cortex from the seizure’s onset.
- Focal or localization-related seizures have previously been referred to as partial seizures.
- Focal seizures originate from a discrete focus limited to one hemisphere in the cerebral cortex.
- Focal seizures are further divided into aware versus unaware and motor versus nonmotor.
- Presence of impaired awareness is defined as the inability to respond normally to exogenous stimuli due to altered awareness and/or responsiveness:
  - Focal seizures with impairment of awareness (formerly “complex partial seizures”)
  - Focal seizures without impairment of awareness (formerly “simple partial seizures”)

EPIDEMIOLOGY

Prevalence
Focal seizures occur in 20/100,000 persons in the United States.

ETIOLOGY AND PATHOPHYSIOLOGY
- Focal seizures begin when a localized seizure focus produces an abnormal, synchronized depolarization that spreads to a discrete portion of the surrounding cortex.
- The area of cortex involved in the seizure determines the symptoms; for example, an epileptogenic focus in motor cortex produces contralateral motor symptoms.
- In some cases, etiology is related to structural abnormalities that are susceptible to epileptogenesis. Most common etiologies vary by life stage:
  - Early childhood: developmental/congenital malformation, trauma
  - Young adults: developmental, infection, trauma
  - Adults 40 to 60 years of age: cerebrovascular insult, infection, trauma
  - Adults >60 years of age: cerebrovascular insult, trauma, neoplasm
- A common cause of focal seizure with impaired awareness is mesial temporal sclerosis.

Genetics
Benign rolandic epilepsy, a form of focal seizure disorder, has an autosomal dominant inheritance pattern with penetrance depending on multiple factors.

RISK FACTORS
- History of traumatic brain injury (TBI)
- Children exposed to a thiamine-deficient formula

COMMONLY ASSOCIATED CONDITIONS
Epilepsy patients have a higher incidence of depression than the general population.
DIAGNOSIS

- Seizure activity usually stereotyped
- Duration: seconds to minutes, unless status epilepticus develops; status epilepticus may present as focal/generalized convulsions/altered mental status without convulsions.
- Focal seizures without impairment of awareness:
  - Formerly referred to as “simple partial seizures”
  - Further characterized by localized symptoms being motor versus nonmotor:
    - Motor onset: Seizure activity in motor strip causes contraction (tonic) or rhythmic jerking (clonic) movements that may involve one entire side of body or may be more localized (i.e., hands, feet, or face).
      - Jacksonian march: As discharge spreads through motor cortex, tonic–clonic activity spreads in predictable fashion (i.e., beginning in hand and progressing up arm and to the face).
    - Nonmotor onset:
      - Todd paralysis: after motor seizure, residual, temporary weakness in the affected area
      - Parietal lobe: sensory loss/paresthesias, dizziness
      - Temporal lobe: déjà vu, rising sensation in epigastrium, auditory hallucinations/forced memories, unpleasant smell/taste
      - Occipital: visual hallucinations
  - Focal seizures with impairment of awareness:
    - Formerly referred to as “complex partial seizures”
    - May have aura; indicates the onset of the seizure
    - Amnesia for the event, postictal confusion
    - Most often, focus is temporal/frontal.
    - Motor manifestations may include dystonic posturing/automatisms (i.e., simple, repetitive movements of face and hands such as lip smacking, picking, or more complex actions such as purposeless walking).
    - Frontal lobe seizure is characterized by brief, bilateral complex movements, vocalizations, often with onset during sleep.

HISTORY

- A detailed description of the seizure should be obtained from an observer.
- Review medication list for drugs that lower seizure threshold (e.g., tramadol, bupropion, theophylline).
- Obtain history of drugs of abuse (e.g., cocaine) because they may lower seizure threshold.
- Review history of any prior TBI.

PHYSICAL EXAM

Include neurologic exam, with attention to lateralizing signs suggestive of structural lesion.

DIFFERENTIAL DIAGNOSIS

- Syncope/postanoxic myoclonus
- Hypoglycemia
- Psychogenic nonepileptic seizure
- For hemiparesis following event
  - Transient ischemic attack
– Hemiplegic migraine

**DIAGNOSTIC TESTS & INTERPRETATION**

- Serum electrolytes, including calcium, magnesium, phosphorus; hepatic function panel; CBC; urinalysis; urine drug screen; levels of antiepileptic drugs (AEDs) for breakthrough seizure; chest x-ray
- Elevated prolactin, if measured within 10 to 20 minutes of suspected seizure, or elevated creatine phosphokinase; if measured within 6 to 24 hours, may help to differentiate generalized/focal seizure from psychogenic nonepileptic seizure (1)[B]
- CSF exam if infection is suspected
- EEG should be considered in patients with first time unprovoked seizure (2)[B].
- Yield of EEG is increased by being obtained in the first 24 hours following seizure and by sleep deprivation.
- EEG will typically show spikes/sharp waves over the seizure focus.
- Frontal lobe seizure focus may be difficult to detect by routine EEG.
- If difficulty with diagnosis, continuous video–EEG monitoring may be appropriate.
- Emergency evaluation of new seizure: CT scan to screen for hemorrhage and stroke
- In patients without recent neuroimaging, consider CT or MRI (2)[B].
- If planning epilepsy surgery, positron emission tomography (PET) scan and/or interictal single-photon emission computed tomography (SPECT) may be of value.
- Magnetoencephalography (MEG) aids in presurgical localization of epilepsy.

**TREATMENT**

**GENERAL MEASURES**

- Ask the patient to maintain a seizure diary.
- Note potential triggers, such as stress, sleep deprivation, drug use, discontinuation of alcohol/benzodiazepines, menses.

**MEDICATION**

- Current guidelines do not recommend for or against starting an AED after a single unprovoked seizure. Patients should be counseled that AEDs will reduce risk of repeat seizure over 2 years but have no effect on long-term remission (3)[C].
- AEDs act on voltage-gated ion channels, affect neuronal inhibition via enhancement of γ-aminobutyric acid (GABA, an inhibitory neurotransmitter), or decrease neuronal excitation. End result is to decrease the abnormal synchronized firing and to prevent seizure propagation.
- 50% of those with newly diagnosed focal seizures respond to, and tolerate, first AED trial. Up to 50% of those who fail the first AED trial will also fail a second AED trial (4)[B].
- Choose AED based on seizure type, side effect profile, and patient characteristics. Increase dose until seizure control is obtained/side effects become unacceptable.
- Attempt monotherapy, but many patients will require adjunctive agents.
- Refractory to medications is defined as failure of at least three anticonvulsants to achieve adequate control.
- AEDs may prevent seizures after a TBI in the short term, although they provide no efficacy in long-term prevention (5)[B].
- Several AEDs induce/inhibit cytochrome P450 enzymes (watch for drug interactions).
First Line
- Carbamazepine: affects sodium channels; side effects include GI distress, hyponatremia, diplopia, dizziness, rare pancytopenia/marrow suppression, and exfoliative rash.
- Oxcarbazepine: affects sodium channels; side effects include dizziness, diplopia, hyponatremia, and headache.
- Lamotrigine: affects sodium channels
  - Side effects include insomnia, dizziness, and ataxia.
  - Risk of Stevens-Johnson reaction (potentially fatal exfoliative rash), especially when given with valproate, requires slow titration
- Levetiracetam: multiple mechanisms; side effects include sedation, ataxia, and irritability.

Second Line
- Phenytoin: affects sodium channels; side effects include ataxia, dizziness, diplopia, tremor, GI upset, gingival hyperplasia, and fever.
- Phenobarbital: multiple mechanisms; side effects include sedation and withdrawal seizures.
- Valproate: multiple mechanisms; side effects include GI upset, weight gain, alopecia, and tremor; less common, thrombocytopenia, hepatitis, pancreatitis
- Topiramate: multiple mechanisms; side effects include anorexia, cognitive slowing, sedation, nephrolithiasis, and anhidrosis.
- Gabapentin: multiple mechanisms; side effects include sedation, dizziness, and ataxia.
- Pregabalin: affects calcium channels; side effects include sedation, dizziness, and weight gain.
- Zonisamide: affects sodium channels
  - Side effects include sedation, anorexia, nausea, dizziness, ataxia, anhidrosis, and nephrolithiasis.
  - Cross-reaction with sulfa allergy

Pregnancy Considerations
- Folate should be prescribed for all women of childbearing age who are taking AEDs. AED therapy during the 1st trimester is associated with doubled risk for major fetal malformations (6% vs. 3%).
- Phenytoin in pregnancy may result in fetal hydantoin syndrome.
- Valproate is associated with neural tube defects and should be avoided in pregnancy when possible.
- Fetal insult from seizures following withdrawal of therapy also may be severe. Risk-to-benefit balance should be evaluated with high-risk pregnancy and neurology consultations. Most patients remain on anticonvulsants.
- AED levels should be monitored at least every trimester.

ISSUES FOR REFERRAL
For refractory seizures, consider referral to an epilepsy specialist.

ADDITIONAL THERAPIES
- Vagal nerve stimulator provides periodic stimulation to vagus nerve; may induce hoarseness, cough, and dysphagia. High-frequency stimulation in adults provides greater reduction in seizure frequency than low-frequency stimulation but also has greater rates of side effects (6) [B].
- Deep brain stimulation may decrease seizure frequency in medically refractive epilepsy, but its efficacy varies by seizure source location.
- Repetitive magnetic transcranial stimulation may reduce the frequency of seizures in individuals with refractory focal seizures.

**SURGERY/OTHER PROCEDURES**
- For refractory focal seizures with identifiable focus
- Preoperative testing, such as Wada test, should be done to decrease likelihood of inducing aphasia and memory loss.
- 34–74% will be seizure free after temporal lobe surgery. Prognosis varies for surgical resection of extratemporal foci.
- Goal of surgical intervention is to reduce reliance on medications; most patients remain on anticonvulsants postoperatively.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Admit for unremitting seizure (focal/secondary generalized status epilepticus).

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Most states have restrictions on driving for those with seizure disorders.
- Depending on seizure manifestation, may also recommend against activities such as swimming, climbing to heights, or operating heavy machinery

**Patient Monitoring**
AED levels if concern over toxicity, noncompliance, or for breakthrough seizures

**DIET**
Ketogenic or low-glycemic index diet may improve seizure control in some patients but is not well tolerated.

**PATIENT EDUCATION**
Avoid potential triggers such as alcohol or drug use and sleep deprivation.

**PROGNOSIS**
- Risk of seizure recurrence: ~30% after first seizure; of these, 50% will occur in the first 6 months, 90% in the first 2 years.
- Depends on seizure type; rolandic epilepsy has a good prognosis; temporal lobe epilepsy is more likely to be persistent.
- ~25–30% of all seizures are refractory to current medications.
- AEDs initiated after an initial seizure have been shown to decrease the risk of seizure over the first 5 years but are not demonstrated to reduce long-term risk of recurrence or mortality.
- The potential for AEDs to confer neuroprotection is under investigation.
- The risk of developing seizure after mild TBI remains high for a long period (>10 years).

**COMPLICATIONS**
- Risk of accidental injury
- Up to 50–60% of individuals with epilepsy will also have a mood disorder, the most common being depression and anxiety.
- 20–30% of individuals with epilepsy will have memory impairment.
REFERENCES

ADDITIONAL READING

CODES

ICD10

- G40.109 Local-rel symptc epi w simp prt seiz, not ntrct, w/o stat epi
- G40.209 Local-rel symptc epi w cmplx prt seiz, not ntrct, w/o stat epi
- G40.119 Local-rel symptc epi w simple part seiz, ntrct, w/o stat epi

CLINICAL PEARLS

- Focal or localization-related seizures have previously been referred to as partial seizures.
- Focal seizures originate from a discrete focus limited to one hemisphere in the cerebral cortex and are further divided into aware versus unaware and motor versus nonmotor, depending on patient presentation.
- It is controversial whether AED treatment is indicated after a first seizure. Treatment should be strongly considered when a clear structural cause is identified/risk of injury from seizure is high (e.g., osteoporosis, anticoagulation).
• An EEG and neuroimaging (CT or MRI) should be considered in evaluating a first unprovoked seizure.
• Most pregnant women should continue anticonvulsant medications. AED levels should be monitored throughout the pregnancy.
• Postictal elevation in prolactin and CPK levels can help distinguish physiologic from psychogenic nonepileptic seizures.
BASICS

DESCRIPTION
- Seizure: sudden and transient symptoms (altered level of consciousness, motor manifestations) due to abnormal or synchronous electrical activity of neuronal networks
- Epilepsy: enduring preposition to generate epileptic seizures; defined as two or more unprovoked seizures apart in a >24-hour period or one unprovoked seizure with a risk of further seizures that is similar to the risk after 2 unprovoked seizures (at least 60%)
- Status epilepticus: epileptic seizure that lasts >5 minutes or multiple seizures without returning to normal between them. Classification: generalized, simple and complex partial, absence, nonconvulsive. Treatment varies depending on type.
- ILAE seizure classification, based on three key features:
  - Seizure origin: focal (previously partial), focal to bilateral, generalized
  - Awareness: aware, focal impaired awareness, generalized
  - Clinical features: motor, nonmotor (absence, behavior, cognitive, autonomic)
- System(s) affected: nervous
- Synonym(s): convulsion; attacks; spells

Pediatric Considerations
Breastfeeding is not contraindicated. Sedation of the infant should be monitored.

Pregnancy Considerations
- Preconception: Certain antiepileptic drug (AED) (P450 inducers) may cause hormonal contraceptive failure.
- Pregnancy: Avoid valproate as possible, due to increased teratogenicity and worse developmental outcomes. Epileptic patients should notify their neurologist before conception, if possible. During pregnancy, monitor AED levels every trimester for dose adjustment, continue folic acid supplementation, and screen for congenital abnormalities.
- Levetiracetam, topiramate, lamotrigine are alternatives for women of childbearing potential (1).

EPIDEMIOLOGY

Incidence
- 200,000 new cases of epilepsy are diagnosed in the United States annually, with 45,000 new cases in children <15 years of age.
- Pediatric (<2 years of age) and older adults (>65 years of age) more commonly present with new-onset seizures
- Predominant sex: male = female

Prevalence
- 2.7 million with seizure disorder
- 4 million people have had ≥1 seizures.
- 326,000 children (≤14 years of age) and 600,000 adults (>65 years of age) have a seizure
ETIOLOGY AND PATHOPHYSIOLOGY

- Synchronous and excessive firing of neurons, resulting in an imbalance of regulatory mechanisms in favor of excitatory activity. Seizures may be triggered by metabolic/medical conditions, but such seizures do not necessarily define the presence of epilepsy.
- Idiopathic
- Hippocampal sclerosis and other neurodevelopmental abnormalities of the brain
- Acute infection (meningitis, abscess, encephalitis)
- Metabolic and endocrine disorders
- Trauma
- Drug and alcohol withdrawal
- Tumor
- Vascular disease, including stroke and vasculitis
- Familial/genetic, infantile, and pediatric seizure syndromes (e.g., Lennox-Gastaut, benign familial, myoclonic epilepsy of infancy)
- Other etiologies (by age of onset)
  - Infancy (0 to 2 years)
    - Hypoxic-ischemic encephalopathy/other injury to cerebral cortex
    - Metabolic: hypoglycemia, hypocalcemia, hypomagnesemia, vitamin B$_6$ deficiency, phenylketonuria
  - Childhood (2 to 10 years): absence or febrile (usually <6 years) seizure
  - Adolescent (10 to 18 years): arteriovenous malformation
  - Late adulthood (>60 years)
    - Prevalence increases with age and is the highest in >65-year-old patients.
    - Degenerative disease, including dementia
    - Most common causes for symptomatic seizures in elderly patients are acute stroke, metabolic disturbances (hypoglycemia, uremia, hepatic failure, electrolyte abnormality), and drugs. Initial diagnostic testing should be focused on these common etiologies.

Genetics

Family history increases risk 3-fold.

RISK FACTORS

History of congenital brain malformations, CNS infections, head trauma, stroke, tumors, neurocognitive degenerative diseases

GENERAL PREVENTION

Take measures to prevent head injuries. Avoid sleep deprivation. Avoid excessive alcohol intake.

COMMONLY ASSOCIATED CONDITIONS

Genetic syndromes (Angelman, tuberous sclerosis, Sturge-Weber), infections, tumors, drug abuse, alcohol and drug withdrawal, trauma, metabolic disorders

DIAGNOSIS

- Physiologic seizures are true cortical events and may require acute intervention.
Psychogenic nonepileptic seizures (PNES) are also a differential diagnosis to consider.

Conventional classification of seizures

- Generalized seizures
  - Tonic–clonic: tonic phase: sudden loss of consciousness; clonic phase: sustained contraction followed by rhythmic contractions of all four extremities; postictal phase: headache, confusion, fatigue; clinically hypertensive, tachycardic, and otherwise hypersympathetic
  - Absence: impaired awareness and responsiveness
  - Atonic: abrupt loss of muscle tone
  - Myoclonic: repetitive muscle contractions

- Febrile seizures
  - Usually ≤6 years
  - Fever without evidence of any other defined cause of seizures
  - Recurrent febrile seizures probably do not increase the risk of epilepsy.

- Focal seizures with retained awareness (previously called simple partial seizures): symptoms vary depending entirely on the part of the cortex involved. Can present with auras and postictal phase.

- Focal seizures with impaired awareness (previously called complex partial seizures): Most common type of seizure in adults with epilepsy. Can stare into space, motionless, or engage in automatisms. Then enters postictal phase.

- Both focal seizures may propagate diffusely to cause bilateral tonic-clonic seizures (previously referred to as secondarily generalized seizures)

- Nonconvulsive status epilepticus: most commonly seen in intensive care unit patients; no tonic–clonic activity seen so must diagnose with bedside electroencephalogram (EEG)

- Status epilepticus: repetitive generalized seizures without recovery between seizures; considered a neurologic emergency

- PNES: nonrhythmic pattern of movement, eye closure during event, anterior tongue biting, history of psychiatric disorders. Patients can also have coexisting epilepsy.

**HISTORY**

- Eyewitness descriptions of event; patient impressions of what occurred before, during, and after the event
- Screen for etiologies, including provoking/ameliorating factors for the event, such as sleep deprivation.
- Ask about bowel/bladder incontinence, tongue biting, other injury, automatisms, or prior seizure activity.

**PHYSICAL EXAM**

Thorough neurologic exam; lateral tongue biting suggestive of generalized seizure, whereas tip of tongue more suggestive of nonepileptic event

**DIFFERENTIAL DIAGNOSIS**

- Syncope, orthostatic hypotension, convulsive syncope
- Transient ischemic attack, stroke
- PNES
- Complicated migraine
- Movement disorders: dystonias, dyskinesias
Sleep disorders: cataplexy, narcolepsy
Psychiatric disorders: conversion, malingering

**DIAGNOSTIC TESTS & INTERPRETATION**
A negative EEG does not rule out a seizure disorder. Interictal EEG sensitivity may be as low as 20%; multiple EEGs (at least three) may increase sensitivity to 80% [2][C].
- Sleep deprivation may be helpful prior to EEG, and hyperventilation and photic stimulation during recording may increase sensitivity.
- Video EEG monitoring is used to differentiate PNES from true cortical events.
- EEG is necessary for diagnosis of nonconvulsive status epilepticus.

**Initial Tests (lab, imaging)**
- Glucose, sodium, potassium, calcium, phosphorus, magnesium, BUN, ammonia; drug and toxin screens
- AED levels (if patient is taking antiepileptic medication)
- CBC, UA, lumbar puncture if needed: Rule out infection.
- Pregnancy test: will influence treatment selection
- Imaging is recommended for new-onset seizures. MRI is preferred to CT scan.
  - CT scan of brain: indicated routinely as initial evaluation, especially in the emergency room
  - Brain MRI: superior in evaluation of the temporal lobes (e.g., mesial temporal sclerosis), stroke, and other structural abnormalities

**Follow-Up Tests & Special Considerations**
- Drugs that may alter lab results: AED therapy may affect the EEG results dramatically.
- Inadequate AED levels may be altered by many medications such as erythromycin, sulfonamides, warfarin, cimetidine, and alcohol.
- Disorders that may alter lab results: Pregnancy decreases serum concentration.
- Bone scan to determine bone mineral density (BMD): generally done if patients are taking older AEDs such as phenytoin and carbamazepine

**Diagnostic Procedures/Other**
Lumbar puncture for spinal fluid analysis may be necessary to rule out meningitis if fever and/or impairment of consciousness are present.

**TREATMENT**
- Older adults are more sensitive to side effects from AEDs; therefore, target dose should be half of dosing for younger population [3][C].
- After presenting with an initial unprovoked seizure, 21–45% of patients will have a recurrence within 2 years [4].
- Starting antiepileptic medications is likely to reduce recurrences of seizures but does not alter long-term outcomes or improve quality of life [4][C].
- Patients with a single unprovoked seizure and associated risk factors that increase recurrence risk up to 60% (abnormal EEG, neurologic exam, or neuroimaging) can potentially benefit from starting therapy.

**MEDICATION**
Anti-epileptic drug (AED) of choice: Select based on type of seizure, potential adverse effects/drug interactions, and cost.

- Monotherapy is preferred whenever possible. Treatment should begin with a single agent and the dose titrated until seizures are controlled or side effects become problematic. Consider a different agent if the first choice is not effective versus adding a second agent.
- Patients treated with loading doses of AED in status epilepticus can be started on maintenance dose of a different AED afterward.

**First Line**

Treatment options include the following:
- Levetiracetam (Keppra): 1,000 to 3,000 mg/day in 2 doses
- Carbamazepine (Tegretol): 100 to 200 mg/day in 1 to 2 doses; therapeutic range, 4 to 12 mg/L
- Lamotrigine (Lamictal): 25 to 50 mg/day; adjust in 100-mg increments every 1 to 2 weeks to 300 to 500 mg/day in 2 doses.
- Oxcarbazepine (Trileptal): 300 mg BID, increase to 300 mg every 3 days; maintenance, 1,200 mg/day
- Lacosamide (Vimpat): 200 to 300 mg/day in 2 doses
- Ethosuximide (Zarontin): 750 to 1,250 mg/day divided BID (childhood absence seizures)
- Generalized status epilepticus: lorazepam 4 mg, fosphenytoin 20 mg/kg load, valproic acid 20 mg/kg load, levetiracetam 40 mg/kg load (5), lacosamide 300 mg load

**Second Line**
- Phenytoin (Dilantin): 200 to 400 mg/day in 1 to 3 doses; therapeutic range, 10 to 20 mg/L
- Valproic acid (Depakene): 750 to 3,000 mg/day in 1 to 3 doses to begin at 15 mg/kg/day; therapeutic range, 50 to 150 mg/L
- Topiramate (Topamax): 50 mg/day; adjust weekly to effect; 400 mg/day in 2 doses, max 1,600 mg/day
- Gabapentin (Neurontin): 1,800 to 3,600 mg in 3 to 4 doses for adjunct therapy
- Pregabalin (Lyrica): 150 to 300 mg/day in 2 to 3 doses
- Zonisamide (Zonegran): 100 to 400 mg in 1 to 2 doses
- Ezogabine (Potiga): 600 to 1,200 mg in 3 doses
- Perampanel (Fycompa): 4 to 12 mg daily
- Clonazepam (Klonopin): 1.5 to 8.0 mg in 2 to 3 doses
- Clobazam (Onfi): 20 to 40 mg in 1 to 2 doses
- Rufinamide (Banzel): 3,200 mg in 2 doses
- Brivaracetam (Briviact) (an analog of levetiracetam): 50 to 200 mg/day in 2 doses
- Perampanel (Fycompa): 4, 8, or 12 mg/day
- Contraindications: Refer to manufacturer’s profile of each drug.
- Precautions: Doses should be based on individual’s response guided by drug levels.
- Consider cautioning about increased risk of suicide, but risk of untreated seizures is far greater than increased risk of suicide.
- Patients are susceptible to sudden unexpected death in epilepsy, possibly due to cardiac arrhythmia.

**ISSUES FOR REFERRAL**

Referral and follow-up frequency is based on severity and patient’s wishes.

**SURGERY/OTHER PROCEDURES**
For patients who fail traditional therapy: lobectomy, resection, laser ablation, and vagus nerve stimulation

COMPLEMENTARY & ALTERNATIVE MEDICINE
- No evidence suggests that any complementary medicines reduce seizures, but they may induce serious drug interactions with prescribed AEDs.
- Psychological therapies may be used in conjunction with AED therapy. Cognitive-behavioral therapy, relaxation, biofeedback, and yoga all may be helpful as adjunctive therapy (6)[C].
- Patients with PNES should be referred for psychotherapy and psychiatry as needed.

ADMSSION, INPATIENT, AND NURSING CONSIDERATIONS
- Outpatient therapy usually is sufficient, except for status epilepticus.
- Admissions to epilepsy monitoring units for video EEG monitoring may benefit patients with events that pose a diagnostic challenge or patients with intractable seizures already on two AEDs.
- Protect the airway and, if possible, protect the patient from physical harm; do not restrain. Administer acute AEDs.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Maintain adequate drug therapy; ensure compliance and/or access to medication. Drug therapy withdrawal and tapering of doses may be considered after a seizure-free 2-year period. Expect a 33% relapse rate in the following 3 years.

Patient Monitoring
- Monitor drug levels and seizure frequency.
- CBC and lab values (e.g., calcium, vitamin D) as indicated; BMD
- Monitor for side effects and adverse reactions.
- All patients currently taking any AED should be monitored closely for notable changes in behavior that could indicate the emergence/worsening of suicidal thoughts/behavior/depression.

DIET
Ketogenic diet may be beneficial in children in conjunction with AED therapy and refractory seizures.

PATIENT EDUCATION
Stress the importance of medication compliance and the avoidance of alcohol and recreational drugs.
- Individuals with uncontrolled seizures should be encouraged to avoid heights and swimming; caution with cooking and unsupervised baths

PROGNOSIS
- Depends on type of seizure disorder: ~70% will become seizure free with appropriate initial
treatment; 30% will continue to have seizures. The number of seizures within 6 months after first presentation is a prognostic factor for remission.

- ~90% who are seen for a first unprovoked seizure attain a 1- to 2-year remission within 4 or 5 years of the initial event (5).
- Life expectancy is shortened in persons with epilepsy.
- The case fatality rate for status epilepticus may be as high as 20%.

SEE ALSO
Seizures, Febrile; Status Epilepticus

CODES
ICD10
- R56.9 Unspecified convulsions
- P90 Convulsions of newborn
- G40.909 Epilepsy, unspecified, not intractable, without status epilepticus

CLINICAL PEARLS
- Initiation of treatment depends on multiple variables, including type of seizure, underlying risk factors, and further risk of recurrence.
- Semiology of event is very important for diagnosis of seizures versus psychogenic nonepileptic seizures. Patients with PNES can have concomitant epileptic seizures.
- Patients in status epilepticus that received loading doses of a certain AED are not required to be on the same medication.
- To consider driving, states require seizure-free period from 3 to 12 months.
SEIZURES, FEBRILE
Swati Avashia, MD, FAAP, FACP, ABIHM ● Stephen W. Line, DO

BASICS

DESCRIPTION
Febrile seizures occur in children ages 6 months to 5 years with fever ≥100.4°F (38°C) and absence of underlying neurologic abnormality, metabolic condition, or intracranial infection. Three types (1,2):

- Simple febrile seizure (SFS) (70–75%; must meet all criteria)
  - Generalized clonic or tonic–clonic seizure activity without focal features
  - Duration <15 minutes
  - Does not recur within 24 hours
  - Resolves spontaneously
  - No history of previous afebrile seizure, seizure disorder, or other neurologic problem
- Complex (CFS) (20–25%; only one criterion must be met)
  - Partial seizure, focal activity
  - Duration >15 minutes but <30 minutes
  - Recurrence within 24 hours
  - Postictal focal neurologic abnormalities (e.g., Todd paralysis) (3)
- Febrile status epilepticus (FSE) (5%)
  - Lasts >30 minutes

EPIDEMIOLOGY

Incidence
- About 500,000 febrile seizures occur in the United States annually
- Peak incidence is 18 months of age (3).
- Only 6% of febrile seizures occur before age 6 months, and 4% occur after age 3 years (4).
- Bimodal seasonal pattern that mirrors peaks of febrile respiratory (November to January) and gastrointestinal infections (June to August) (3)

Prevalence
- 2–5% of children in the white population ages 6 months to 3 years in United States and Western Europe (4)
- Cumulative incidence varies in other populations (0.5–14%) (2)

ETIOLOGY AND PATHOPHYSIOLOGY
Cause of febrile seizures is likely multifactorial (1):
- Lower baseline seizure threshold in affected age group
- Familial genotypes may influence seizure thresholds.
- Fever may alter ion channel activity, causing increased neuronal excitability.
- Cytokines released in infection increase neuronal activity.

Genetics
Evidence for genetic association:
- Greater concordance in monozygotic than dizygotic twins
25–40% of cases have positive family history (4).
- Previously affected sibling increases risk
- Having two affected parents doubles a child’s risk
- Mode of inheritance is multifactorial, although autosomal dominant inheritance reported (3)
- Several rare familial epileptic syndromes present with febrile seizure

**RISK FACTORS**
- Any condition causing fever. Height of temperature elevation increases risk.
- Risk increases with number of affected first-degree (O.R. = 4.5%) and second-degree relatives (O.R. = 3.6%) (1)
- Risk is increased for males (2)
- Recent vaccination
  - Possible increased risk with MMR and DTaP vaccinations, but it’s unclear (4), and absolute vaccination-associated risk is very low. As febrile seizures are benign, benefits of vaccination outweigh risks.
  - No evidence of increased risk with influenza vaccination (1)
- Prenatal exposure to alcohol and tobacco, child care center attendance, premature birth, developmental delay, and prolonged NICU stay
- Perhaps increased risk with iron deficiency anemia (5)

**GENERAL PREVENTION**
Prevention is not usually indicated given the benign nature of this condition, lack of effective interventions, and side effects of prophylactic medications.

**COMMONLY ASSOCIATED CONDITIONS**
- Viral infections: human herpesvirus 6 (HHV-6), influenza, parainfluenza, adenovirus, and respiratory syncytial virus (RSV)
  - HHV-6 infection found in 30% of FSE in one study (4)
- Bacterial infections: otitis media, pharyngitis, urinary tract infection (UTI), pneumonia, and gastroenteritis (specifically with Shigella)

**DIAGNOSIS**

**HISTORY**
- History of present illness:
  - Description and duration of seizure:
    - Febrile seizures are generalized with clonic or tonic–clonic activity
    - Absence, myoclonic, atonic, and focal seizures are atypical of febrile seizures and warrant further evaluation
  - Presence of postictal state (such as weakness or paralysis)
  - Number of seizures in last 24 hours
  - Altered mentation
  - Symptoms of underlying infection or neurologic deficits
- Past medical history:
  - Immunization status, recent vaccines
  - Pre-existing conditions: developmental delay, cerebral palsy, metabolic disorders, prior seizures or head injury
– Recent antibiotic course
• Family history: febrile seizures, afebrile seizures, epilepsy, metabolic disorders, and other neurologic conditions
• Social history: factors concerning for child abuse

PHYSICAL EXAM
• Vital signs should be stable and consistent with intercurrent febrile illness; unstable vital signs or toxic appearance warrants further evaluation
• Evaluate for focal neurologic deficits
• Assess for signs of meningitis
• Identify cause of fever
• Assess for nonaccidental trauma with skin inspection, palpation for occult trauma, and retinal exam

DIFFERENTIAL DIAGNOSIS
• Seizures due to other etiology: meningitis, encephalitis, primary epilepsy, neonatal seizure, Dravet syndrome, intracranial mass, nonaccidental trauma, electrolyte abnormality, hypoglycemia, metabolic disorder
• Seizure mimics: rigors, crying, breath-holding spell, choking episode, tic disorder, parasomnia, arrhythmia, metabolic disorder, dystonic reaction

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
• Routine laboratory tests are not recommended if the child is well appearing (3)[C].
• Urinalysis only if indicated by current UTI screening guidelines (3)[B]. Rates of UTI in children with SFS are comparable to febrile children without seizure.
• Blood glucose is not routinely recommended (3)[B].
• Lumbar puncture
  – Perform if there is concern for meningitis or other intracranial pathology based on history and exam (3)[B]
    o In studies of SFS conducted since initiation of routine infant vaccination against Haemophilus influenzae, rates of acute bacterial meningitis were very low (0–0.8%).
    o Bacterial meningitis is rare in children with febrile seizures who return to baseline.
    o In infants ages 6 to 12 months, consider lumbar puncture if the child has not been vaccinated against H. influenzae or Streptococcus pneumoniae according to schedule (3)[C].
    o Signs suggesting increased likelihood of meningitis include toxic appearance, altered sensorium, focal neurologic deficits, meningeal signs, bulging fontanel, and petechial rash. Signs of meningitis in children younger than 6 months may be unreliable (1)[C].
  – Consider lumbar puncture for children with fever and seizure who have recently been treated with antibiotics (3)[C].
  – The yield of lumbar puncture in children with CFS is very low, and the rate of acute bacterial meningitis in U.S. patients with CFS is too low to routinely recommend lumbar puncture.
• Neuroimaging is not routinely recommended to identify the cause of a febrile seizure (3)[B].
  – Studies demonstrate limited utility of emergent imaging in patients who meet criteria for CFS, thus head CT scan is not routinely recommended (2)[B].
– Consider imaging if bleed or structural lesion is suspected.

• Check for anemia if iron deficiency is suspected (5)[C].

**Diagnostic Procedures/Other**

• EEG is not recommended in neurologically normal children presenting with SFS (3)[B].

• There is mixed evidence for use of EEG after CFS; some recommend outpatient EEG on follow-up because EEGs can show generalized slowing for 24 hours after initial presentation and up to 7 days after FSE (3)[C].

• Outpatient EEG can be considered in children with multiple risk factors for seizure disorders.
  – Risk factors include family history, developmental delay, and more than one defining feature of CFS.

---

## TREATMENT

Most seizures are self-limited and end before EMS arrives or the child arrives at the hospital.

### GENERAL MEASURES

• Acute seizure management (1)
  – Airway: Position the patient laterally, suction secretions, and place a nasopharyngeal airway if needed
  – Breathing: Administer oxygen for cyanosis; consider bag-mask ventilation or intubation for inadequate ventilation
  – Circulation: Establish IV access if first-line buccal or nasal midazolam is not effective

• Antipyretics are helpful in overall patient comfort and symptom management

• Provide supportive care and treat underlying infection if necessary

### MEDICATION

#### First Line

• Treat seizures of ≥5 minutes duration with anticonvulsants (3)[C]:
  – Out of hospital: rectal diazepam 0.5 mg/kg, buccal midazolam 0.2–0.4 mg/kg, or nasal midazolam 0.2 mg/kg
  – In hospital: IV or IM lorazepam 0.05–0.1 mg/kg or IV diazepam 0.1–0.2 mg/kg

• Risk of adverse effects is low when dosed appropriately (1).
  – Lorazepam and diazepam have similar rates of seizure cessation and respiratory depression profile

#### Second Line

IV phenobarbital 15–20 mg/kg, IV phenytoin 15–20 mg/kg, IV/IM fosphenytoin 20 mg PE/kg

### ISSUES FOR REFERRAL

SFS does not require a pediatric neurology referral.

### COMPLEMENTARY & ALTERNATIVE MEDICINE

Some studies document low zinc levels in blood and CSF samples in children with febrile seizures compared to those with afebrile seizures.

• A Cochrane review found no benefit to zinc supplementation for prevention of febrile seizure.

### ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Unstable vital signs
- Abnormal and concerning findings on history or physical exam
- Prolonged seizure requiring anticonvulsants, especially when there is a prolonged return to baseline
- Persistent change in mental status
- Inpatient management of underlying condition is required.
- Unreliable patient follow-up

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Anticonvulsant prophylaxis during subsequent febrile episodes:
  - American Academy of Pediatrics recommends against prophylaxis with anticonvulsants due to an unacceptable risk–benefit ratio (3)[B].
  - Intermittent oral and rectal diazepam are effective in reducing recurrence of simple and complex febrile seizures but are not recommended due to the benign nature of febrile seizures and because so many febrile seizures precede the development of the fever (3)[B].

- Antipyretic prophylaxis during subsequent febrile episodes (3)[A]:
  - Rectal acetaminophen given every 6 hours over a 24-hour period may reduce short-term recurrence of seizures during the same fever episode, but not future seizure episode recurrence (1).
  - Ibuprofen and acetaminophen are no more effective than placebo in preventing subsequent episode recurrence (6).

**PATIENT EDUCATION**

There is frequently a high degree of parental anxiety associated with febrile seizures.

- Educate parents that febrile seizures are a benign condition and treatment is often unnecessary (7).

- Febrile seizures do not cause brain damage, have a low risk for sequelae, and do not have a negative impact on intellect, behavior, or risk of death (4)[B].

- Prepare for a high probability of recurrence. If seizure recurs, position the child safely in a semiprone position and do not intervene inappropriately.

- Time the seizure; call rescue if the child turns blue, has difficulty breathing, or the seizure lasts >5 minutes.

- If seizure spontaneously resolves in <5 minutes and the child is well but sleepy, seek immediate attention, but calling rescue is not necessary.

- After a seizure, a child should be placed in a recovery position.

**PROGNOSIS**

- Recurrence:
  - Estimates of rates vary (30–50%).
  - 10% will experience three or more febrile seizures (3,7).
  - Factors associated with seizure recurrence include age <18 months at time of first episode, affected first-degree relative, history of CFS, lower peak temperatures, and shorter duration of fever prior to seizure (3).

- Intellectual and behavioral outcomes
– Febrile seizures do not impact IQ, behavior, academic performance, or attention span (4).
– Outcomes in children with single and multiple febrile seizures are similar.

● Subsequent development of epilepsy (3)
– Risk of epilepsy after SFS is close to the overall rate in the general population
– Risk is up to 7% if multiple SFS, age <12 months and a short duration of fever prior to seizure onset.
– Factors associated with increased risk include CFS, family history of epilepsy or febrile seizures, cerebral palsy, developmental delay, low birth weight, and prematurity.

● Mortality:
– No increased risk for SIDS in siblings of children who have febrile seizures

COMPLICATIONS
Seizure-related injury, aspiration pneumonia, side effects of prescribed medications or diagnostic procedures, and subsequent parental perception of the child as being vulnerable, especially during subsequent fevers

REFERENCES

ADDITIONAL READING

CODES
ICD10
● R56.00 Simple febrile convulsions
● R56.01 Complex febrile convulsions
● G40.901 Epilepsy, unsp, not intractable, with status epilepticus
CLINICAL PEARLS

- Febrile seizures are generally benign and without sequelae.
- Evaluate for underlying causes such as meningitis, trauma, or other intracranial pathology.
- For SFS, routine labs, lumbar puncture, neuroimaging studies, and EEG are not recommended in the absence of clinical suspicion of serious underlying pathology.
- Prophylaxis with anticonvulsants or antipyretics during subsequent febrile episodes is not recommended.
SEROTONIN SYNDROME
Michael T. Partin, MD  Karl T. Clebak, MD, FAAFP  Munima Nasir, MD

BASICS

DESCRIPTION
- A potentially life-threatening drug-induced syndrome that results from synaptic increase in serotonin (5-hydroxytryptamine [5-HT]) concentrations and stimulation of peripheral and central nervous system (CNS) serotonergic receptors
- Classically characterized by a triad of symptoms that include mental status change, neuromuscular hyperactivity, and autonomic instability
- Onset is usually within 24 hours with 60% of cases occurring within 6 hours of exposure to, or change in, dosing of a serotonergic agent. Rarely, cases have been reported weeks after discontinuation of serotonergic agents.
- It is a concentration-dependent toxicity that can develop in any individual who has ingested drug combinations that synergistically increase synaptic 5-HT.
- Serotonin toxicity occurs in three main settings: (i) therapeutic drug use, which often results in mild to moderate symptoms; (ii) intentional overdose of a single serotonergic agent, which typically leads to moderate symptoms; and (iii) as the result of a drug interaction between numerous serotonergic agents (most commonly, selective serotonin reuptake inhibitors [SSRIs], serotonin noradrenergic reuptake inhibitors [SNRIs], and monoamine oxidase inhibitors [MAOIs]), most often associated with severe serotonin toxicity.

Geriatric Considerations
Increased risk through polypharmacy given frequent use of serotonergic analgesics, antibiotics, and antidepressants

Pediatric Considerations
- Serotonin syndrome has similar manifestations in children and adults.
- Aside from altering medication dosing, general management is unchanged in pediatric patients.
- Consider toxic ingestion of serotonergic agents prescribed to caregivers of pediatric patients.
- Symptoms in neonates may include tremors, increased muscle tone, jitteriness, shivering, feeding/digestive disturbances, irritability, agitation, sleep disturbances, increased reflexes, excessive crying, and respiratory disturbances.

Pregnancy Considerations
- Serotonin levels are increased from baseline during an uncomplicated pregnancy with preeclamptic patients demonstrating a 10-fold increase in serotonin levels.
- 3rd-trimester exposure to SSRIs has been associated with transient neonatal complications that may reflect either acute drug withdrawal or serotonergic toxicity.

EPIDEMIOLOGY
Seen in about 14–16% of SSRI overdose patients

Incidence
Approximately 100,000 adverse events, including deaths, are reported annually with antidepressant use. Most of which are associated with SSRIs, either alone or in combination with other drugs. In a 2008 study, SSRIs alone were responsible for adverse events in 18.8% of cases, with 55.7% due to intentional causes, 39.5% unintentional, and remainder of causes unknown. Of patients reporting adverse effects with SSRIs, 46.6% had symptoms requiring hospitalization, and significant toxic effects occurred in 90 patients with two resultant deaths \((1)\)\[A\].

The incidence of serotonin syndrome is rising because serotonergic agents are increasingly used in clinical practice and in combination with other serotonergic agents. However, the true incidence is unclear due to potential misdiagnosis and unreported mild cases.

- Predominant age: affects all age groups
- Predominant sex: male = female

**ETIOLOGY AND PATHOPHYSIOLOGY**

- Increased synaptic 5-HT or agonist concentration as a result of one or more of the following mechanisms: (i) decreased 5-HT breakdown (e.g., MAOI), (ii) decreased 5-HT reuptake (e.g., SSRI), (iii) increased 5-HT agonists (e.g., tryptophan), (iv) increased 5-HT release (e.g., amphetamines), and (v) CYP2D6 and CYP3A4 inhibitors (e.g., erythromycin)
- Risk is mediated in a dose-related manner to the action of 5-HT/5-HT agonists on 5-HT\(_{1A}\) and/or 5-HT\(_{2A}\) receptors.
- A number of drugs are associated with serotonin syndrome, which usually involves combination with an SSRI. These include SSRIs (e.g., citalopram, escitalopram, fluoxetine, fluvoxamine, paroxetine, sertraline); MAOIs; SNRIs ( duloxetine, venlafaxine, desvenlafaxine); tricyclic antidepressants (e.g., amitriptyline); other antidepressants (nefazodone, trazodone); anxiolytic (buspirone); lithium; triptans; antiemetics (ondansetron, granisetron); other medications, such as metoclopramide, cyclobenzaprine, L-dopa; dietary supplements (tryptophan); herbal supplements (St. John’s wort, nutmeg); methylene blue; and drugs of abuse (e.g., methylenedioxymethamphetamine [MDMA], cocaine, D-lysergic acid diethylamide [LSD], and amphetamine) \((2)\)\[A\].

**Genetics**

Unknown

**RISK FACTORS**

- Polypharmacy
- Serotonergic agents
- Recent dose change or overdose of drugs associated with serotonin syndrome
- Comorbid conditions leading to polypharmacy
- The greatest number of adverse events has been shown to be associated with SSRIs in combination with other substances, and the combination of SSRIs and MAOIs carries the greatest risk of developing serotonin toxicity.

**GENERAL PREVENTION**

- Consider drug–drug interactions when a multidrug regimen is required and avoid if possible.
Caution patients about taking SSRIs with OTC medications (e.g., dextromethorphan) or herbal supplements (e.g., St. John’s wort) prior to consulting a physician.

Clinician education and continual improvement in use of health information technology to identify potential drug–drug interactions

Avoid serotonergic agents for nonpsychiatric disorders (e.g., tramadol for pain relief).

**DIAGNOSIS**

Serotonin syndrome is a clinical diagnosis.

Hunter Toxicity Criteria Decision Rules (3) aid in the diagnosis of clinically significant serotonin toxicity (sensitivity, 84%; specificity, 97%). A patient who took a serotonergic agent must have one of the following:

- Spontaneous clonus
- Inducible clonus with agitation or diaphoresis
- Ocular clonus with agitation or diaphoresis
- Hypertonia and hyperthermia (temperature >38°C [100.4°F]) with inducible clonus or ocular clonus (3)[A]
- Tremor and hyperreflexia

**HISTORY**

- Obtain a thorough drug history including prescriptions, OTC remedies, dietary and herbal supplements, and illicit drugs. Ask about dose, formulation, and recent changes.
- Review comorbidities (e.g., depression and chronic pain).
- Address possibility of drug overdose and obtain collateral information if intentional overdose is suspected.
- Elicit description of symptoms, including onset and progression.

**PHYSICAL EXAM**

Neuromuscular findings are seen in over half of patients with serotonin syndrome. Initially, patients can develop a peripheral tremor, confusion, and ataxia; systemic signs are next (e.g., agitation, diaphoresis, hyperreflexia, and shivering). If it worsens, the severe signs of fever, jerking, and diarrhea may develop.

- Tachycardia, hypertension, and hyperthermia (≥40°C [≥104°F] in severe cases)
- Neuromuscular abnormalities
  - Mild: hyperreflexia, myoclonus, and tremor all greater in lower extremities; bilateral Babinski sign
  - Moderate: opsoclonus, spontaneous or inducible clonus (involuntary muscle contractions, most commonly tested by rapid dorsiflexion of foot)
  - Severe: rigidity, respiratory failure, tonic–clonic seizure
- Autonomic dysfunction:
  - Mild: diaphoresis, mydriasis, tachycardia
  - Moderate: hyperactive bowel sounds, diarrhea, nausea, vomiting, hyperthermia (<40°C [<104°F])
  - Severe: hyperthermia (≥40°C [≥104°F]), rapidly changing blood pressure (BP)
- Mental status changes:
  - Mild: anxiety, akathisia (restlessness), insomnia
  - Moderate: agitation
Severe cases have led to altered level of consciousness, rhabdomyolysis, metabolic acidosis, and disseminated intravascular coagulation (DIC).

**DIFFERENTIAL DIAGNOSIS**
- Neuroleptic malignant syndrome (NMS): lead pipe rigidity and extrapyramidal features without clonus
- Anticholinergic fever (e.g., benztrapine, diphenhydramine, oxybutynin, nifedipine, famotidine, atropine, scopolamine; plant poisoning from belladonna/“deadly nightshade,” datura, henbane, mandrake, brugmansia): urinary retention, decreased bowel sounds, normal reflexes
- Malignant hyperthermia: generally following administration of anesthetics or depolarizing muscle relaxants
- Heat stroke
- CNS infection (meningitis, encephalitis)
- Sympathomimetic toxicity (cocaine, methamphetamine, PCP)
- Nonconvulsive seizures
- Hyperthyroidism (thyroid storm)
- Tetanus
- Rabies
- Acute baclofen withdrawal

**DIAGNOSTIC TESTS & INTERPRETATION**
- No single test confirms diagnosis of serotonin syndrome.
- Serum serotonin levels do not correlate with clinical findings.
- Nonspecific lab findings may include:
  - Elevated WBC count
  - Elevated creatine phosphokinase (CK or CPK)
  - Decreased serum bicarbonate
  - Elevated hepatic transaminases
- In severe cases, the following complications may develop:
  - DIC
  - Metabolic acidosis
  - Rhabdomyolysis
  - Renal failure
  - Myoglobinuria
  - Acute respiratory distress syndrome (ARDS) (3)[A]
- Consider urine toxicology screening for illicit drugs

**TREATMENT**
- Discontinuation of all serotonergic agents is primary management regardless of severity.
- Supportive care is the mainstay of therapy. This includes administration of oxygen and aggressive IV fluids, continuous cardiac monitoring, monitoring urine output, and stabilizing vital signs.
  - Benzodiazepines may be effective for the management of agitation.
  - Administration of serotonin antagonists: Cyproheptadine may be useful if supportive
measures and sedation (benzodiazepines) are unable to control agitation and correct vital signs. This agent does not reduce the duration of serotonin syndrome.

- Mild cases (afebrile, tachycardia, shivering, diaphoresis, mydriasis, hyperreflexia, intermittent tremor or myoclonus)
  - Discontinue precipitating agent(s).
  - Supportive care
  - Sedation
  - Observe for 12 to 24 hours.

- Moderate cases (temperature >38°C (>100.4°F), autonomic instability, hyperactive bowel sounds, diarrhea, diaphoresis, ocular clonus, hyperreflexia, tremor, mild agitation, or hypervigilance)
  - Discontinue precipitating agent(s).
  - Supportive care
  - Sedation
  - Aggressive treatment of autonomic instability
  - Treatment with cyproheptadine should be initiated if agitation and vital sign abnormalities are unimproved with benzodiazepines and supportive care.
  - Hypotension from MAOI interactions should be treated with low doses of direct-acting sympathomimetics (e.g., norepinephrine, phenylephrine, epinephrine); indirect serotonin agonists, such as dopamine, should be avoided.
  - Severe hypertension and tachycardia should be treated with short-acting agents, such as nitroprusside or esmolol.
  - Avoid use of longer acting agents, such as propranolol, to prevent hypotension and falsely lowering heart rate, which can be used to monitor treatment response.
  - Observe for 12 to 24 hours.

- Severe cases (temperature >41.1°C (>105.98°F), autonomic instability, delirium, muscular rigidity, and hypertonicity)
  - Discontinue precipitating agent(s).
  - Immediate sedation
  - Endotracheal intubation as clinically indicated
  - Paralysis as clinically indicated (maintained with nondepolarizing continuous paralytic agents such as vecuronium, cisatracurium, rocuronium)
  - Succinylcholine should not be used in cases of rhabdomyolysis to avoid exacerbation of hyperkalemia (5)[A].
  - Antipyretic medications are not effective (4)[A]; the increased body temperature is due to muscle activity, not an alteration in the hypothalamic set point.
  - Avoid physical restraints because it can worsen hyperthermia and lactic acidosis in agitated patients (5)[A].

**MEDICATION**

- Benzodiazepines: may be used to manage agitation in serotonin syndrome and also may correct mild increases in BP and heart rate. Use with caution in patients with delirium, given the known paradoxical effect of exacerbating delirium.
- Cyproheptadine (Periactin): Consider use if benzodiazepines and supportive measures are unable to control agitation and correct vital signs:
  - Adults: initial dose 12 mg PO (can also be crushed and given via nasogastric [NG] tube) followed by 2 mg q2h until clinical response observed; 12 to 32 mg of drug may be required
in a 24-hour period.
- Children
  - <2 years: 0.06 mg/kg q6h
  - 2 to 6 years: 2 mg q6h
  - 7 to 14 years: 4 mg q6h
- Unlikely to be effective in patients who have received activated charcoal
- Pregnancy Category B

Use of antipsychotics with 5-HT\textsubscript{2A} antagonist activity, such as olanzapine and chlorpromazine, is not recommended (4)[B].

ISSUES FOR REFERRAL
- Psychiatry: for assistance with medication management and follow-up care (inpatient psychiatric care vs. outpatient psychiatric follow-up)
- Toxicology/clinical pharmacology service
- Poison control center

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Patients with known/suspected serotonin syndrome should be admitted to a medical inpatient unit for observation.
- Discharge criteria
  - Mental status has returned to baseline.
  - Stable vital signs
  - No increase in clonus
  - Close patient follow-up is ensured.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- In mild cases of serotonin toxicity, address risks and benefits of restarting offending agents. Serotonergic medications need to be titrated slowly, and patients must have close outpatient follow-up with physician.
- If patient developed severe serotonin syndrome, the offending agent should likely not be resumed unless precipitant for serotonin syndrome is found (e.g., combination with another serotonin agonist); the patient can be carefully monitored, or there is clear benefit versus risk of restarting the medication.

PROGNOSIS
- Generally favorable with early recognition of the syndrome and prompt initiation of treatment
- Most cases resolve within 24 hours of discontinuation of serotonergic agents; this can be longer depending on the drug’s half-life:
  - MAOIs can result in toxicity for several days.
  - SSRIs can result in toxicity for up to several weeks after discontinuation.
- ICU admission is often indicated in severe cases.

COMPLICATIONS
- Adverse outcomes, including death, are usually the consequence of poorly treated hyperthermia and may include acute renal failure, acute respiratory distress syndrome,
arrhythmia, coma, disseminated intravascular coagulation, seizure, metabolic acidosis, multiorgan failure, myoglobinuria, respiratory arrest, and rhabdomyolysis.

- Nonhyperthermic patients who survive typically do not have long-term sequelae.

CODES

ICD10
G25.79 Other drug induced movement disorders

CLINICAL PEARLS

Consider serotonin syndrome in patients with recent use of a serotonergic agent (particularly if multiple proserotonergic agents are involved) presenting with unexplained tachycardia, hypertension, hyperthermia, clonus, hyperreflexia, and change in mental status.
SEXUAL DYSFUNCTION IN WOMEN
Esther Guard, DO

BASICS
- Very common: ~40% of women surveyed in the United States have sexual concerns.
- May present as a lack of sexual desire, impaired arousal, inability to achieve orgasm or pain with sexual activity, and may be lifelong or acquired

DESCRIPTION
- Female sexual interest or arousal disorder—lack of or significantly reduced sexual interest or arousal as manifested by three of the following:
  - Absent or reduced interest in sexual activity
  - Absent or reduced sexual or erotic thoughts or fantasies
  - No or reduced initiation of sexual activity and unreceptive to partner’s attempts to initiate
  - Absent or reduced sexual excitement or pleasure during sexual activity in almost all (75–100%) of sexual encounters
  - Absent or reduced sexual interest or arousal in response to any internal or external sexual or erotic cues
  - Absent or reduced genital or nongenital sensation during sexual activity in almost all (75–100%) of sexual encounters
- Female orgasmic disorder—presence of either of the following in almost all (75–100%) occasions of sexual activity:
  - Marked delay in, marked infrequency of, or absence of orgasm
  - Markedly reduced intensity of orgasmic sensations
- Genito-pelvic pain or penetration disorder—persistent or recurrent difficulties with one or more of the following:
  - Vaginal penetration during intercourse
  - Marked vulvovaginal or pelvic pain during intercourse or penetration attempts
  - Marked fear or anxiety about vulvovaginal or pelvic pain in anticipation of, during, or because of vaginal penetration
  - Marked tensing or tightening of pelvic floor muscles during attempted vaginal penetration

ALERT
Symptoms must be present for ≥6 months; cause clinically significant distress or impairment; and not be better explained by a nonsexual mental disorder, a consequence of severe relationship distress, or other significant stressors

- System(s) affected: nervous; reproductive; genitourinary; psychiatric
- Synonym(s): hypoactive sexual desire disorder; sexual aversion disorder; female sexual arousal disorder; inhibited female orgasm

EPIDEMIOLOGY
In two large studies, approximately 40% of women reported sexual problems.

Incidence
Sexual problems are highest in women aged 45 to 64 years and then decline secondary to
changes in sexual-related personal distress.

**Prevalence**
Low sexual desire is the most common manifestation, followed by difficulty with orgasm, difficulty with arousal, and sexual pain.

**ETIOLOGY AND PATHOPHYSIOLOGY**
The pathophysiology of sexual dysfunction is complex and multifactorial because it can be the result of any etiology that interferes with the female sexual response cycle (desire, arousal, orgasm, and resolution). Phases can vary in sequence, overlap, or be absent during all or some sexual encounters.

- **Biologic**
  - Disorders of the hypothalamic-pituitary-adrenal system, hormonal imbalance/disorders of ovarian function, menopause (surgical or natural), chronic illness (vascular disease, diabetes mellitus, and malignancy)
  - Prescription medications (SSRIs, MAOIs, TCAs, β-blockers)
  - Thyroid disease
  - Neuromuscular disease (multiple sclerosis, spinal cord damage)
- **Psychological**
  - Anxiety/depression
  - Maladaptive thoughts/behaviors
  - Interrelational difficulties
  - Body image issues
  - Drug and alcohol abuse
  - Sexual abuse

**RISK FACTORS**
- Advancing age/menopause
- Previous sexual trauma
- Lack of knowledge about sexual stimulation and response
- Chronic medical problems
  - Depression, anxiety, chronic pain syndromes, and other psychiatric disorders
  - Cardiovascular disease
  - Endocrine disorders
  - Dermatologic disorders
  - Neurologic disorders
  - Cancer
- Gynecologic issues
  - Childbirth
  - Pelvic floor or bladder dysfunction
  - Endometriosis
  - Uterine fibroids
  - Chronic vulvovaginal candidiasis/vaginal infections
  - Female genital mutilation
- Relationship factors such as couple discrepancies in expectations and/or cultural backgrounds and attitudes toward sexuality in family of origin
- Medications or substance abuse
COMMONLY ASSOCIATED CONDITIONS
- Marital/relationship discord
- Depression

DIAGNOSIS
- Female sexual dysfunction is diagnosed by utilizing a validated sexual function screening instrument and a structured interview, including detailed medical and sexual history, to confirm diagnosis.
  - Female Sexual Function Index
  - Brief Index of Sexual Functioning for Women
  - Brief Sexual Symptom Checklist
  - Decreased Sexual Desire Screener
- The diagnosis requires that the sexual problem be recurrent or persistent and causes personal distress rather than be due solely to partner or relationship issues.

HISTORY
- Detailed sexual history
  - Degree of personal distress
  - Lifelong versus acquired problem
  - Situational versus generalized problem
  - Cultural/societal beliefs regarding sexuality
  - History of sexual trauma
  - Concerns about safety, pregnancy, or STIs
  - Concerns regarding privacy
- Interpersonal relationship factors
  - Current relationship status
  - Family dysfunction
- Physiologic/biologic history
  - Urinary/anal incontinence
  - Medications (including herbal and OTC)
  - Pregnancy/childbirth history
  - Infertility
  - Menopausal status (natural, surgical, or postchemotherapy)
  - STIs and vaginitis
  - Pelvic surgery, injury, or cancer
  - Chronic pelvic pain
  - Abnormal genital tract bleeding
- Psychological history
  - Low self-image
  - Anxiety
  - Depression
  - Negative past sexual experiences
  - Substance misuse/abuse

PHYSICAL EXAM
Most commonly, patients have a normal physical exam.
- Assess for anatomic abnormalities.
- Assess for scars or evidence of trauma.
- Assess for vaginal atrophy, adequate estrogenization.
- Assess for infection.
- Recognize signs of anxiety, apprehension, and pain during the speculum and pelvic exam.

General physical exam, signs of chronic disease

DIFFERENTIAL DIAGNOSIS
- Medication side effects
- Vaginitis
- Decreased vaginal lubrication secondary to hormonal imbalance
- Decreased sensation secondary to nerve injury
- Multiple sclerosis
- Anatomic abnormalities
- Abdominal surgery (which can interfere with pelvic innervation)
- Depression
- Marital dysfunction, including domestic violence
- Pregnancy
- Pseudodyspareunia (use of complaint of pain to distance self from partner)

DIAGNOSTIC TESTS & INTERPRETATION
Laboratory studies are rarely helpful. There are no reliable correlations between serum hormone levels and sexual dysfunction.

Initial Tests (lab, imaging)
As needed to identify infections and other medical causes

TREATMENT
- Set realistic goals and expectations (1)[C].
- Address underlying medical and psychiatric conditions (2)[C].
- Review basic sex education, sexual response, heterogeneity of normal response, and sexual activity other than intercourse (1)[C].
- Education on communication
- Educate on healthy lifestyle, including diet, exercise, sleep, avoidance of tobacco, and reduced alcohol use (1)[C].
- Vaginal moisturizers and lubricants
- Cognitive-behavioral therapy (CBT) (individual or couples) to target maladaptive thoughts and behaviors and to disrupt the dysfunctional cycle (2)[C]
- Mindfulness-based CBT (1)[C]
- Sex therapy: sensate focus, systematic desensitization exercises, homework exchanging physical touch with partner, scheduled attempt of sexual activity 3 times per week, or directed masturbation alone (2,3)[C]
- Physical therapy/biofeedback (3)[C]

MEDICATION
Sexual dysfunction is often a multifactorial psychosocial condition. Using medications does not usually address the cause of the problem and can, in some cases, make the condition worse.

- **Bupropion (1)[C]:** adjunct for SSRI-induced sexual dysfunction. Improves sexual arousal and orgasm but not desire. Dose: bupropion SR 150 mg orally once or twice daily

- **Flibanserin (2)[C],[4][A]:** possible improvement in sexual desire. Clinical improvement versus placebo is minimal, and side effects are common. Mechanism of action: 5-HT$_{1A}$ agonist and 5-HT$_{2A}$ antagonist. Dose: 100 mg at bedtime; FDA-approved for premenopausal women with hypoactive sexual desire

- **Estrogen replacement with or without progestins (1,3)[C],[5][A]:** may improve sexual desire, vaginal atrophy, and clitoral sensitivity. Vaginal estrogen therapy (preferred route of administration) is available in cream, vaginal tablet, or ring form.

- **Ospemifene (1,3)[C]:** selective estrogen receptor modulator FDA-approved for dyspareunia due to vulvo- or vaginal atrophy in postmenopausal women. Dose: ospemifene 60 mg orally once daily

- **Testosterone (1,2,3,6)[B]**
  - Use in premenopausal women not supported by data
  - In naturally or surgically postmenopausal women, adding short-term testosterone to hormone replacement may increase desire.
  - >6 months use lacks data on safety and effectiveness.
  - Side effects: hirsutism, androgenic alopecia, acne, decreased HDL, liver dysfunction; not FDA-approved for sexual dysfunction in women
  - Contraindicated in breast or endometrial cancer, thromboembolic disease, or coronary artery disease
  - Dose: oral methyltestosterone 1.25 to 2.50 mg/day (1/10 of men’s dose) or topical (patch, gel)

- **Dehydroepiandrosterone (DHEA) (6)[C]:** vaginal formulation 6.5 mg FDA-approved for dyspareunia due to vaginal atrophy in postmenopausal women

- **Phosphodiesterase type 5 (PDE5) inhibitors:** adjunct for SSRI- or SNRI-induced sexual dysfunction

**ISSUES FOR REFERRAL**
Consider referral for CBT, marriage/couples counseling, pelvic floor therapy, or sex therapy.

**ADDITIONAL THERAPIES**
- Smoking cessation and reduction of alcohol intake
- For childhood trauma: scripting, psychotherapy, cognitive restructuring
- For prescription-drug causes: reduced dosages or change to different medication

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Zestra for women botanical feminine massage oil: Small trial showed increased arousal, desire, genital sensation, ability to have orgasm, and sexual pleasure.
- Yohimbine: not recommended, potentially dangerous
- Ginseng and St. John’s wort: no evidence to support treatment of sexual dysfunction

**ONGOING CARE**
DIET
Weight reduction if overweight or obese

PATIENT EDUCATION
- American Association of Sexuality Educators, Counselors, and Therapists: www.aasect.org
- National Women’s Health Resource Center: www.healthywomen.org
- North American Menopause Society: www.menopause.org
- National Vulvodynia Association: www.nva.org

PROGNOSIS
Lack of desire is most difficult type to treat with <50% success. Treatment is most successful with multidisciplinary approach.

REFERENCES

ADDITIONAL READING
Female sexual dysfunction is a common, complex, multifactorial problem. Usually, patients with sexual dysfunction have a normal physical exam. Symptoms of sexual dysfunction peak during perimenopause between the ages of 45 and 64 years. Combination of behavioral, physical, and medical therapy leads to greater treatment success.
There is rarely a simple “fix” with a medication.
SHOULDER PAIN
J. Herbert Stevenson, MD • Jonathan W. Smits, MD

BASICS

DESCRIPTION
- Shoulder pain commonly affects patients of all ages.
- Causes include acute trauma, overuse during sports, and activities of everyday living.
- Age plays an important role in determining the etiology of shoulder pain.
- Onset and characteristics of pain, mechanism of injury, weakness, and functional limitation help narrow the differential diagnosis.

EPIDEMIOLOGY
- Shoulder pain accounts for 16% of all musculoskeletal complaints.
- The lifetime prevalence of shoulder pain is ~70%.
- Predominant etiology varies with age:
  - <30 years: shoulder instability
  - 30 to 60 years: rotator cuff (RTC) disorder, impingement syndrome, partial tears
  - >60 years: full-thickness tear, glenohumeral OA

Incidence
The incidence of shoulder pain is 7 to 25 cases per 1,000 patients, with a peak incidence in the 4th to 6th decades.

ETIOLOGY AND PATHOPHYSIOLOGY
Pathology varies with cause:
- Trauma—fracture, dislocation, ligament/tendon tear, acromioclavicular (AC) separation
- Overuse—RTC pathology, biceps tenosynovitis, bursitis, muscle strain, apophyseal injuries
- RTC disorders most commonly result from repetitive overhead activity, leading to RTC impingement with a three-stage progression:
  - Stage I: tendinopathy
  - Stage II: partial RTC tear
  - Stage III: full-thickness RTC tear
- Subacromial bursitis can occur with RTC disorders but is rarely an isolated diagnosis.
- Age related: In pediatric athletes, instability and physeal injuries are more common. With increasing age, the incidence of AC and glenohumeral joint OA, adhesive capsulitis, and RTC tear rises.
- Rheumatologic: rheumatoid arthritis, polymyalgia rheumatica, fibromyalgia
- Referred pain: neck, gallbladder, diaphragm

RISK FACTORS
- Repetitive overhead activity
- Overhead and upper extremity weight-bearing sports (baseball, softball, swimming, tennis, volleyball)
- Weight lifting: AC joint disorders
- Rapid increases in training frequency or load (often associated with improper technique)
• Muscle weakness or imbalance
• Trauma or fall onto the shoulder
• Diabetes, thyroid disorders, and other autoimmune diseases; female gender; and age 40 to 60 years are risk factors for adhesive capsulitis.

**GENERAL PREVENTION**
• Maintain strength and range of motion (ROM).
• Avoid repetitive overhead activities (pitch counts).
• Proper technique (pitching, weight lifting)

**DIAGNOSIS**

**HISTORY**
- Pain characteristics location:
  - Superior: AC pathology, trapezius strain
  - Lateral: RTC pathology
  - Anterior: biceps tenosynovitis
  - Diffuse pain: RTC pathology, adhesive capsulitis, glenohumeral OA
- Descriptors:
  - Night pain, worse lying on affected side: RTC pathology, adhesive capsulitis, glenohumeral OA
  - Stiff shoulder, limited ROM: adhesive capsulitis, glenohumeral OA
- Aggravating movements:
  - Cross-body adduction, “scarf test”: AC pathology
  - Abduction/external rotation (reaching behind): instability, RTC pathology, glenohumeral OA
  - Overhead activity: RTC pathology, AC pathology, labrum pathology, glenohumeral OA
  - Turning neck, pain past elbow: cervical pathology
- Mechanism of injury:
  - Forceful abduction and external rotation: traumatic shoulder instability/dislocation
  - Fall directly onto lateral shoulder: AC joint sprain, clavicular fracture
  - Repetitive overhead activity: RTC pathology
  - Fall on outstretched hand (FOOSH): shoulder separation; forearm/wrist fracture
- Age:
  - Shoulder instability (subluxation, dislocation, multidirectional instability) is the most common cause of shoulder pain in young athletes (<30 years old).
  - RTC disorders are the most common cause of shoulder pain in patients >30 years old.
  - Severity of RTC disorder increases with age.
  - Older patients (>60 years old) commonly have OA.
  - Trauma in a young person <40 years is more commonly associated with dislocation/subluxation. In patients >40 years, trauma is more commonly associated with RTC tear.

**PHYSICAL EXAM**
• Three main joints combine to create the shoulder: glenohumeral, AC, sternoclavicular.
• Four RTC muscles/tendons (SITS): supraspinatus (abduction), infraspinatus (external rotation),
teres minor (external rotation, adduction), and subscapularis (adduction, internal rotation)

- Observe face and shoulder movements as patient disrobes, moves arm, and shakes hand.
- Inspect for malalignment, muscle atrophy, asymmetry, erythema, ecchymosis, and swelling. Scapular winging suggests long thoracic nerve or muscular (trapezius, serratus anterior) dysfunction. Prominent scapular spine with scalloped infraspinatus fossa suggests infraspinatus atrophy.
- Palpate SC joint, AC joint, acromion, biceps tendon for tenderness, warmth, bony step-offs.
- Evaluate active and passive ROM and flexibility.
- Decreased active and passive ROM is more common with adhesive capsulitis. Normal abduction is to 180 degrees.
- Pain from 60 to 180 degrees suggests subacromial impingement; 120 to 180 degrees suggests AC joint pathology (1).
- Mildly decreased active and/or passive ROM may also indicate glenohumeral OA.
- Decreased active ROM with full passive ROM: RTC pathology
- Evaluate for muscle strength, including grip, biceps, triceps, and deltoïd.
- Test RTC strength: supraspinatus (empty can test), infraspinatus/teres minor (resisted external rotation, external lag test), subscapularis (lift-off test, belly press, resisted internal rotation)
- Pain with RTC strength testing indicates RTC pathology. Weakness could suggest tear.
- Special diagnostic tests
  - Neer RTC impingement test: Examiner stabilizes the scapula and internally rotates the patient’s arm and forcefully flexes the shoulder through the full ROM or until the patient reports pain.
  - Hawkins RTC impingement test: Examiner forcefully internally rotates the shoulder with the elbow, and shoulder flexed to 90 degrees to the end of ROM or until the patient reports pain.
  - Drop-arm test for RTC tear: positive if patient is unable to smoothly control the lowering of their arm or to hold the arm in 90 degrees of abduction
  - Cross-arm adduction is painful in AC joint arthritis.
  - Speed test for biceps tendinopathy: With arm 30 degrees of flexion and palm supinated, patient attempts to flex the elbow against resistance. Pain over biceps is positive.
  - Yergason test for biceps tendinopathy: With the elbow stabilized to the patient’s side and flexed to 90 degrees, place the patient’s forearm in pronation and resist against supination.
  - Apprehension, relocation test for anterior glenohumeral joint instability: Examiner supports the elbow of the patient and with the other hand holding the wrist, slowly externally rotates the humerus with the shoulder at 90 degrees abduction, patient apprehensive with maneuver.
  - Sulcus sign for inferior glenohumeral joint instability: Examiner pulls down with the hand grasping the subject’s elbow, positive if significant inferior movement of the arm, relative to shoulder.
  - O’Brien, clunk test for labral pathology: performed with arm at 90 degrees of flexion, 10 degrees of adduction, thumb pointed down (arm in internal rotation), examiner resists flexion distally. Pain/clicking is positive.
  - Spurling test for cervical pathology: rotation of head toward side of symptoms along with neck extension with applied downward force to reproduce radicular symptoms

Differential Diagnosis

- Fracture (clavicle, humerus, scapula), contusion
RTC disorder: impingement, tear, calcific tendinitis
Subacromial bursitis
Scapulothoracic dyskinesis
AC joint pathology (AC separation/OA, osteolysis)
Biceps tenosynovitis or tear
Acromial apophysitis or os acromiale
Glenohumeral joint OA
Glenohumeral joint instability (acute dislocation or chronic multidirectional instability)
Adhesive capsulitis
Labral tear or associated bony pathology
Muscle strain (trapezius, deltoid, biceps)
Cervical radiculopathy
Other: autoimmune, rheumatologic, referred pain, septic joint (biliary/splenic, cardiac, pneumonia/lung mass)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Shoulder pain can be accurately diagnosed with a careful history and physical exam. Symptoms should be evaluated in the context of the patient as a whole.
A history of significant trauma, prolonged symptoms, or red flags (older age, fever, rest pain) suggests a need for imaging.
Adults with nontraumatic shoulder pain of <4 weeks duration may not require initial imaging.
Plain radiographs are first line:
- Assess for fracture, degenerative changes, signs of dislocation (Bankart, Hill-Sachs deformity), signs of large RTC tear (sclerosis, proximal migration of humeral head), anatomic deformities contributing to impingement, and masses (tumor, cyst).
- Standard views: anteroposterior, scapular Y, axillary
EMG study of the upper extremity may help differentiate referred cervical pain and brachial plexopathy from a primary shoulder disorder.
Obtain ECG if any suspicion for cardiac etiology.
Serologic tests if autoimmune etiology is suspected.

Follow-Up Tests & Special Considerations
CT or MRI can rule out an occult fracture.
MRI is gold standard for noninvasive soft tissue imaging, including RTC, biceps tendon.
MR arthrogram may be necessary to assess for labral tears.
Ultrasound (US) can assess for RTC tears, biceps tendinopathy, and AC joint pathology.
US is operator dependent but in the hands of a good technician can be equivalent to MRI in detecting full-thickness tears (sensitivity 92%, specificity 94%) and partial-thickness tears (sensitivity 67%, specificity 94%) (1).

Diagnostic Procedures/Other
Consider diagnostic arthroscopy after failing conservative management if structural injury is suspected.

Test Interpretation
Tendinosis rather than tendinitis is common with stage I impingement.
Capsular scarring is the hallmark of adhesive capsulitis.
RTC enthesisophytes visualized with calcific tendinitis
Tear enlargement and pain development in asymptomatic tears are more common with involvement of the dominant shoulder.

TREATMENT

- Treatment is based on underlying diagnosis.
- In general, conservative therapy includes activity modification, analgesics, and/or anti-inflammatory medicines in association with appropriate rehabilitative programs.
- Physical therapy almost always required for full resolution

MEDICATION

First Line
- Analgesics and anti-inflammatory medications for symptomatic relief include NSAIDs, such as ibuprofen, naproxen, and meloxicam. Acetaminophen may also be used especially if the patient has a history of a GI bleed.
- Corticosteroid injections (subacromial, glenohumeral, AC, subscapular bursa) can be used to acutely relieve pain due to RTC pathology, adhesive capsulitis, OA, or scapulohoracic dyskinesis (2)[A].
- Steroid injections can improve ability to engage in rehabilitative activities.
- US guidance improves accuracy of anatomic placement of corticosteroid injections; long-term outcomes similar between US-guided versus nonguided versus NSAID; use after 6 to 8 weeks.

ISSUES FOR REFERRAL

- If etiology remains unclear, patient is not responsive to conservative care for complicated or displaced fractures.
- Full-thickness RTC tears >1 cm (acute or chronic) in patients <65 years old or any tear with significant changes in functional status require surgical referral. These tears have a high rate of progression, fatty infiltration, or retraction with nonoperative care (3).

ADDITIONAL THERAPIES

- Physical therapy can benefit persistent RTC disorders, adhesive capsulitis, and shoulder instability.
- Manual therapy and exercises may improve pain and increase function in RTC disease.
- Manual manipulative therapy (MMT) by chiropractors, osteopathic physicians, or physical therapists improves pain with adhesive capsulitis, RTC, and soft tissue disorders. In adhesive capsulitis, MMT is generally less effective than glucocorticoid injections at 6-week mark, but both have similar long-term outcomes. Acupuncture may improve short-term pain and function in RTC impingement (4)[A].

SURGERY/OTHER PROCEDURES

- Surgery is recommended for shoulder pain caused by acute displaced fractures, large RTC tears (criteria as above). It may also be recommended for multiple shoulder dislocation in patients <20 years of age.
- Surgery can be considered for shoulder pain unresponsive to conservative measures >3 to 6 months. Surgery is not more effective than active nonsurgical treatment in impingement syndrome (5)[A].
Platelet-rich therapies need more conclusive evidence before routine use in treatment of MSK soft tissue injuries.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Acupuncture may help with acute shoulder pain. There is no conclusive evidence for the effectiveness of acupuncture.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Limit overhead activity to reduce impingement symptoms.

PATIENT EDUCATION
Refer to specific diagnosis for shoulder pain.

PROGNOSIS
Shoulder pain generally has a favorable outcome with conservative care, but recovery can be slow, with 40–50% of patients complaining of persistent pain or recurrence at 12 months.

REFERENCES

ADDITIONAL READING
CLINICAL PEARLS

- RTC disorders (tendinopathy, tears) are the most common cause of shoulder pain in individuals >30 years of age.
- Shoulder instability (acute dislocation/subluxation or chronic instability) is the most common source of shoulder pain in individuals <30 years of age.
- Patients with diabetes are at increased risk for adhesive capsulitis.
- Most patients do well with a structured program of pain control and rehabilitation.
SINUSITIS
Chirag N. Shah, MD  Grant Wei, MD, FACEP

BASICS
DESCRIPTION
- Acute sinusitis is a symptomatic inflammation of ≥1 paranasal sinuses of <4 weeks duration resulting from impaired drainage and retained secretions accompanied by obstruction, facial pain/pressure/fullness, or both. Because rhinitis and sinusitis usually coexist, “rhinosinusitis” is the preferred term.
- Disease is subacute when symptomatic for 4 to 12 weeks, recurrent acute when ≥4 annual episodes without persistent symptoms in between, and chronic when symptomatic for >12 weeks.
- Uncomplicated rhinosinusitis has no extension of inflammation beyond paranasal sinuses and nasal cavity.
- System(s) affected: head/eyes/ears/nose/throat (HEENT), pulmonary

EPIDEMIOLOGY
- Affects 1 in 8 adults accounting for >30 million individuals in the United States each year diagnosed with rhinosinusitis
- Diagnosis of acute bacterial rhinosinusitis remains the fifth leading reason for prescribing antibiotics.
- 0.5–2% of viral rhinosinusitis episodes have a bacterial superinfection.
- Viral cause in 90–98% of cases

Incidence
Incidence is highest in early fall through early spring (related to incidence of viral upper respiratory infection [URI]). Adults have two to three viral URIs per year; 90% of these colds are accompanied by viral rhinosinusitis. It is the fifth most common diagnosis made during family physician visits.

ETIOLOGY AND PATHOPHYSIOLOGY
- Important features
  - Inflammation and edema of the sinus mucosa
  - Obstruction of the sinus ostia
  - Impaired mucociliary clearance
- Secretions that are not cleared become hospitable to bacterial growth.
- Inflammatory response (neutrophil influx and release of cytokines) damages mucosal surfaces.
- Viral: vast majority of cases (rhinovirus; influenza A and B; parainfluenza virus; respiratory syncytial, adeno-, corona-, and enteroviruses)
- Bacterial (complicates 0.5–2% of viral cases)
  - More likely if symptoms worsen within 5 to 6 days after initial improvement
  - No improvement within 10 days of symptom onset
  - >3 to 4 days of fever >102°F and facial pain and purulent nasal discharge
- Streptococcus pneumoniae, Haemophilus influenzae, and Moraxella catarrhalis are the most common bacterial pathogens.
– Often overdiagnosed, which leads to overuse of and increasing resistance to antibiotics
– Methicillin-resistant Staphylococcus aureus present in 0–15.9% of patients
• Fungal: seen in immunocompromised hosts (uncontrolled diabetes, neutropenia, use of corticosteroids) or as a nosocomial infection

**Genetics**
No known genetic pattern

**RISK FACTORS**
• Viral URI
• Allergic rhinitis
• Asthma
• Cigarette smoking
• Dental infections and procedures
• Anatomic variations
  – Tonsillar and adenoid hypertrophy
  – Turbinate hypertrophy, nasal polyps
  – Cleft palate
• Immunodeficiency (e.g., HIV)
• Cystic fibrosis (CF)

**GENERAL PREVENTION**
• Hand washing to prevent transmission of viral infection
• Childhood vaccinations up to date
• Avoid close contacts with symptomatic individuals.
• Avoid smoking and exposure to secondhand smoke.

**DIAGNOSIS**
• History and physical exam suggest and establish the diagnosis but are rarely helpful in distinguishing bacterial from viral causes.
• Use a constellation of symptoms rather than a particular sign or symptom in diagnosis.

**HISTORY**
• Symptoms somewhat predictive of bacterial sinusitis (1)[C]
  – Worsening of symptoms >5 to 6 days after initial improvement
  – Persistent symptoms for ≥10 days
  – Persistent purulent nasal discharge
  – Unilateral upper tooth or facial pain
  – Unilateral maxillary sinus tenderness
  – Fever
• Associated symptoms
  – Headache
  – Nasal congestion
  – Retro-orbital pain
  – Otalgia
  – Hyposmia
– Halitosis
– Chronic cough

• Symptoms requiring urgent attention
  – Visual disturbances, especially diplopia
  – Periorbital swelling or erythema
  – Altered mental status

**PHYSICAL EXAM**

• Fever
• Edema and erythema of nasal mucosa
• Purulent discharge
• Tenderness to palpation over sinus(es)
• Pain localized to sinuses when bending forward
• Transillumination of the sinuses may confirm fluid in sinuses (helpful if asymmetric; not helpful if symmetric exam).

**Pediatric Considerations**

• Sinuses are not fully developed until age 20 years. Maxillary and ethmoid sinuses, although small, are present from birth.
• Because children have an average of six to eight colds per year, they are at risk for developing sinusitis.
• Diagnosis can be more difficult than in adults because symptoms are often more subtle.

**DIFFERENTIAL DIAGNOSIS**

• Dental disease
• CF
• Wegener granulomatosis
• HIV infection
• Kartagener syndrome
• Neoplasm
• Headache, tension, or migraine

**DIAGNOSTIC TESTS & INTERPRETATION**

Diagnostic tests are not routinely recommended; no diagnostic tests can adequately differentiate between viral and bacterial rhinosinusitis (2)[C].

• None indicated in routine evaluation
• Routine use of sinus radiography discouraged because of the following:
  – ≥3 clinical findings have similar diagnostic accuracy as imaging.
  – Imaging does not distinguish viral from bacterial etiology.
• Limited coronal CT scan can be useful in recurrent infection or failure to respond to medical therapy.

**Diagnostic Procedures/Other**

Sinus CT if signs suggest extrasinus involvement or to evaluate chronic rhinosinusitis

**Test Interpretation**

• Inflammation, edema, thickened mucosa
• Impaired ciliary function
Metaplasia of ciliated columnar cells
Relative acidosis and hypoxia within sinuses
Polyps

**TREATMENT**

Most cases resolve with supportive care (treating pain, nasal symptoms). Antibiotics should be reserved for symptoms that persist >10 days, onset with severe symptoms (high fever, purulent nasal discharge, facial pain) for at least 3 to 4 consecutive days, or worsening signs/symptoms that were initially improving (1,2)[C].

**GENERAL MEASURES**

- Hydration
- Steam inhalation 20 to 30 minutes TID
- Saline irrigation (neti pot) or nose drops
- Sleep with head of bed elevated.
- Avoid exposure to cigarette smoke or fumes.
- Avoid caffeine and alcohol.
- Antibiotics are indicated only when findings suggest bacterial infection.
- Analgesics, nonsteroidal anti-inflammatory drugs (NSAIDs)
- Acute viral sinusitis is self-limiting; antibiotics should not be used.

**MEDICATION**

**First Line**

- Decongestants
  - Pseudoephedrine HCl
  - Phenylephrine nasal spray (limited use)
  - Oxymetazoline nasal spray (e.g., Afrin) (not to be used >3 days)
- Analgesics
  - Acetaminophen
  - Aspirin
  - NSAIDs
- Antibiotics
  - Antibiotics can shorten time to cure but only in 5 to 11 people per 100 (3)[A]; most improve without antimicrobial therapy.
  - Reserve antibiotic use for patients with moderate to severe disease.
  - Choice should be based on understanding of antibiotic resistance in the community.
  - Infectious Disease Society of America (IDSA) recommends the following (1)[C]:
    - Start antibiotics as soon as clinical diagnosis of acute bacterial sinusitis is made.
    - Use amoxicillin-clavulanate rather than amoxicillin alone.
    - Amoxicillin-clavulanate 875/125 mg q12h; 2 g orally BID in geographic regions with high rates of resistant S. pneumoniae
    - Doxycycline: 100 mg PO BID an alternative to amoxicillin-clavulanate for initial therapy (adults only)
    - Trimethoprim-sulfamethoxazole (TMP/SMX) and 3rd-generation cephalosporins not recommended due to high rate of resistance (1)[C]
Treat for 5 to 7 days in adults if uncomplicated bacterial rhinosinusitis (IDSA low-moderate-quality evidence). Treat for 10 to 14 days in children if uncomplicated bacterial rhinosinusitis (IDSA low-moderate-quality evidence).

- American Academy of Pediatrics recommends the following (1)[C]:
  - Amoxicillin: 45 to 90 mg/kg/day in 2 divided doses if uncomplicated acute bacterial sinusitis in children
  - Amoxicillin-clavulanate: 80 to 90 mg/6.4 mg/kg/day in 2 divided doses for children with severe illness, recent antibiotics, or attending daycare
  - Levofloxacin: 10 to 20 mg/kg/day max 750 mg/day if history of type 1 hypersensitivity to PCN (1)[C]
  - Clindamycin (30 to 40 mg/kg/day) + cefixime (8 mg/kg/day in 2 divided doses) or cefpodoxime (10 mg/kg/day in 2 divided doses) (1)[C] for non–type 1 PCN allergy
  - Ceftriaxone: 50 mg/kg IM single dose if not able to tolerate oral meds (4)[C]

- Because allergies may be a predisposing factor, some patients may benefit from use of the following agents:
  - Oral antihistamines
    - Loratadine (Claritin), fexofenadine (Allegra), cetirizine (Zyrtec), desloratadine (Clarinex), or levocetirizine (Xyzal)
    - Chlorpheniramine (Chlor-Trimeton)
    - Diphenhydramine (Benadryl)
  - Leukotriene inhibitors (Singulair, Accolate), especially in patients with asthma
  - Nasal steroids (i.e., fluticasone [Flonase])

Second Line
- Levofloxacin (Levaquin): 750 mg/day for 5 days or moxifloxacin 400 mg/day for 5 to 7 days (adults only) (1)[C]

- If no response to first-line therapy after 72 hours
  - Broaden antibiotic coverage or switch to a different class; evaluate for resistant pathogens or other causes for treatment failure (i.e., noninfectious etiology); fluoroquinolones as above

- Note: Bacteriologic failure rates of up to 20–25% are possible with use of azithromycin and clarithromycin.

- If lack of response to 3 weeks of antibiotics, consider the following:
  - CT scan of sinuses
  - Ear/nose/throat (ENT) referral

ISSUES FOR REFERRAL
Complications or failure of treatment

ALERT
- Meta-analyses have demonstrated no benefit of newer antibiotics over amoxicillin or doxycycline.
- Antibiotics recommendations vary with different guidelines. Patients seen by specialists are different from those in a primary care setting. Patients usually do not have complicated sinusitis in primary care setting.
  - American Academy of Otolaryngology—Head and Neck Surgery Foundation (2)[C] recommends the following:
    - Consider watchful waiting without antibiotics in patients with uncomplicated mild illness
(mild pain and temperature <101°F) with assurance of follow-up within 7 days.

- PCV-13 pneumococcal vaccine can be helpful in reducing chronic sinusitis in children (5)[B].
- Use of intranasal steroids small but significant improvement in symptoms when used alone or in combination with antibiotics (6)[A]
- Precautions
  - Decongestants can exacerbate hypertension.
  - Intranasal decongestants should be limited to 3 days to avoid rebound nasal congestion.

**Pregnancy Considerations**
- Nasal irrigation with saline, pseudoephedrine, most antihistamines, and some nasal steroids are safe during pregnancy and lactation.
- Antibiotics safe in pregnancy and lactation
  - Amoxicillin, amoxicillin-clavulanate, cephalosporins
- Antibiotic contraindicated: doxycycline, fluoroquinolones
- Antibiotic safe in lactation but not pregnancy: levofloxacin

**SURGERY/OTHER PROCEDURES**
- If medical therapy fails, consider sinus irrigation.
- Functional endoscopic sinus surgery is the preferred treatment for medically recalcitrant cases.
- Absolute surgical indications
  - Massive nasal polyposis
  - Acute complications: subperiosteal or orbital abscess, frontal soft tissue spread of infection
  - Mucocele or mucopyocele
  - Invasive or allergic fungal sinusitis
  - Suspected obstructing tumor
  - Cerebrospinal fluid rhinorrhea

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Hospitalization for complications (e.g., meningitis, orbital cellulitis or abscess, brain abscess)

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Return if no improvement after 72 hours or no resolution of symptoms after 10 days of antibiotics.

**PATIENT EDUCATION**

**PROGNOSIS**
Alleviation of symptoms within 72 hours with complete resolution within 10 to 14 days

**COMPLICATIONS**
- Serious complications are rare.
- Meningitis, orbital cellulitis, brain abscess
- Cavernous sinus thrombosis
- Osteomyelitis, subdural empyema
REFERENCES

ADDITIONAL READING

CODES

ICD10
- J01.90 Acute sinusitis, unspecified
- J01.00 Acute maxillary sinusitis, unspecified
- J01.20 Acute ethmoidal sinusitis, unspecified

CLINICAL PEARLS

- When bacterial infection is present, patients recover somewhat more quickly with antibiotics, but the majority will recover with symptomatic treatment alone, and accurate diagnosis of bacterial sinusitis is very difficult.
- Multiple meta-analyses have demonstrated no benefit of newer antibiotics over amoxicillin or doxycycline.
- Antibiotic number needed to treat is 10 to 19 for shortening time course, whereas number needed to harm is 8, from medication side effects.
- Significant patient symptom relief with nasal saline spray or drops or irrigation (neti pot)
SJÖGREN SYNDROME
Mariya Milko, DO, MS

BASICS
- Chronic inflammatory disorder characterized by lymphocytic infiltrates in exocrine organs
- Typically presents with diminished salivary and lacrimal gland function, resulting in sicca symptoms such as dry eyes (xerophthalmia), dry mouth (xerostomia), and parotid enlargement
- Extraglandular manifestations: arthralgia, myalgia, Raynaud phenomenon, pulmonary disease, GI disease, leukopenia, anemia, lymphadenopathy, vasculitis, renal tubular acidosis, lymphoma, CNS involvement with longitudinal transverse myelitis (>4 vertebral segments), and optic neuritis associated with anti–aquaporin-4 antibodies, PNS involvement with small fiber neuropathy
- Primary Sjögren: not associated with other diseases; HLA-DRB1*0301 and HLA-DRB1*1501 are the most common.
- Secondary Sjögren: complication of other rheumatologic conditions, most commonly rheumatoid arthritis; associated with HLA-DR4
- First described by Swedish ophthalmologist Henrik Sjögren

EPIDEMIOLOGY
Incidence
Annual incidence: ~4/100,000. Primary Sjögren syndrome (SS) is one of the most common autoimmune diseases, affecting 1–4% of population.
- All races are affected.
- Predominant sex: female > male (9:1)
- Predominant age: can affect patients of any age but is most common in the elderly; onset typically in the 4th to 5th decades of life

Prevalence
SS affects 1 to 4 million people in the United States.

ETIOLOGY AND PATHOPHYSIOLOGY
- Multifactorial systemic autoimmune process characterized by infiltration of glandular tissue by CD4 T lymphocytes
- Theorized that glandular epithelial cells present antigen to the T cells inducing cytokine production. There is also evidence for B-cell activation, resulting in autoantibody production and an increased incidence of B-cell malignancies.
- Etiology is unknown. Estrogen may play a role because SS is more common in women. Exogenous factors such as viral proteins (EBV, HCV, HTLV-1) have also been implicated.

Genetics
- A familial tendency suggests a genetic predisposition.
- Associations in the HLA regions HLA-DQA1*0501, HLA-DQB1*0201, and HLA-DRB*0301 are the strongest genetic risk factors for SS.

RISK FACTORS
There are no known modifiable risk factors.

**GENERAL PREVENTION**
- No known prevention. Complications can be prevented by early diagnosis and treatment.
- Oral health providers play a key role in early detection and management of salivary dysfunction (1)[C].

**COMMONLY ASSOCIATED CONDITIONS**
Secondary SS associated with rheumatoid arthritis, scleroderma, systemic lupus erythematosus (SLE), polymyositis, HIV, hepatitis C, MCTD, PBC, hypergammaglobulinemic purpura, necrotizing vasculitis, autoimmune thyroiditis, chronic active hepatitis, mixed cryoglobulinemia

**Pregnancy Considerations**
Pregnant SS patients with anti-SSA Abs have increased risk of delivering fetus with skin rash and 3rd-degree heart block.

**DIAGNOSIS**

2016 ACR/EULAR classification criteria (2)[A]:
- Based on five objective tests/items
- Inclusion criteria applicable if the patient is positive for one ocular/oral dryness symptom based on the AECG questions or at least one positive domain from the EULAR SS disease activity index questionnaire and a total score of ≥4 from the following:
  - Positive serum anti-SSA/Ro antibody—3 points
  - Focal lymphocytic sialadenitis with a focus score ≥1 foci/4 mm² from labial salivary gland biopsy—3 points
  - Abnormal ocular staining score of ≥5 or van Bijsterveld score of ≥4—1 point
  - Schirmer test result of ≤5 mm/5 min—1 point
  - An unstimulated salivary flow rate of ≤0.1 mL/min—1 point

- Ocular signs and symptoms
  - Troublesome dry eyes daily for ≥3 months
  - Recurrent sandy/gritty ocular sensation
  - Use of tear substitute ≥3 times per day

- Oral signs and symptoms
  - Daily symptoms of dry mouth for ≥3 months
  - Recurrent feeling of swollen salivary glands
  - Need to drink liquid to help swallow dry foods

- Other manifestations: chronic arthritis, type 1 RTA, tubular interstitial nephritis, rheumatoid arthritis, vasculitis, vaginal dryness, pleuritis, pancreatitis

**HISTORY**
- Decreased tear production; burning, scratchy sensation in eyes
- Difficulty speaking/swallowing, dental caries, xerotrachea
- Enlarged or intermittent swelling of parotid glands (bilateral)
- Dyspareunia; vaginal dryness
- From consensus criteria and EULAR questionnaire:
  - (1) Have you had daily, persistent, troublesome dry eyes for ≥3 months?
– (2) Do you have a recurrent sensation of sand or gravel in the eyes?
– (3) Do you use tear substitutes >3 times a day?
– (4) Have you had a daily feeling of dry mouth for >3 months?
– (5) Do you frequently drink liquids to aid in swallowing dry food?

PHYSICAL EXAM

● Eye exam: dry eyes (keratoconjunctivitis sicca), decreased tear pool in the lower conjunctiva, dilated conjunctival vessels, mucinous threads, and filamentary keratosis (slit-lamp examination)
● Mouth exam: dry mouth (xerostomia); decreased sublingual salivary pool (tongue may stick to the tongue depressor); frequent oral caries (sometimes in unusual locations such as the incisor surface and along the gum line); dark red tongue from prolonged xerostomia
● Ear, nose, and throat exam: parotid enlargement, submandibular enlargement
● Skin exam: nonpalpable or palpable vasculitic purpura (typically 2 to 3 mm in diameter and on the lower extremities)

DIFFERENTIAL DIAGNOSIS

● Causes of ocular dryness: hypovitaminosis A, decreased tear production unrelated to autoimmune process, chronic blepharitis or conjunctivitis, impaired blinking (i.e., due to Parkinson disease or Bell palsy), infiltration of lacrimal glands (i.e., amyloidosis, lymphoma, sarcoidosis), low estrogen levels
● Causes of oral dryness: anticholinergic medications, sialadenitis due to chronic obstruction, chronic viral infections (e.g., hepatitis C or HIV), radiation of head/neck
● Causes of salivary gland swelling: unilateral: obstruction, chronic sialadenitis, bacterial infection, neoplasm; bilateral (asymmetric): IgG4-related disease, HIV; bilateral (symmetric): hepatic cirrhosis, DM, anorexia/bulimia, acromegaly, alcoholism, hypolipoproteinemia, chronic pancreatitis, acute or chronic viral infection (i.e., mumps, Epstein-Barr virus [EBV], coxsackievirus, echovirus, granulomatous diseases (i.e., tuberculosis, sarcoidosis)

DIAGNOSTIC TESTS & INTERPRETATION

● Schirmer test (<5-mm wetness after 5 minutes)
● Rose Bengal test (slit lamp)
● Minor salivary gland biopsy (gold standard)
● Auto antibodies: +ANAs (95%), +RF (75%)
● In primary SS: +anti-Ro (anti-SSA, 56%) and +anti-La (anti-SSB, 30%)

Initial Tests (lab, imaging)

Preliminary lab workup

● Basic labs: CBC with differential, BUN/creatinine (Cr), AST/ALT, ESR, C-reactive protein (CRP), urinalysis
● Special labs: ANA, rheumatoid factor (RF), anti-Ro/SSA, anti-La/SSB, ESR, CRP
● Anti-SSA and anti-SSB antibodies present in 33–74% and 23–52% of SS patients, respectively
● Other autoantibodies-muscarinic type 3 receptor (M3R) and anti-α-fodrin are being explored with good specificity (3)[A].

Imaging may include:

– Imaging for xerostomia: salivary gland scintigraphy (insensitive but highly specific)
– Parotid gland sialography (should not be used in acute parotitis)
– MRI (correlates well with salivary gland biopsy)
A novel diagnostic tool is salivary gland US (SGUS), which is noninvasive and highly specific for salivary gland involvement in SS (4)[A].

**Diagnostic Procedures/Other**
- Salivary gland biopsy: used to confirm suspected diagnosis of SS or to exclude other causes of xerostomia and bilateral glandular enlargement
- Parotid biopsy if malignancy is suspected
- Lymph node biopsy to rule out pseudolymphoma or lymphoma if suspected

**Test Interpretation**
- Salivary gland histology shows focal collections of lymphocytes; immunocytology shows CD4+ T-cell lymphocyte predominance.
- SGUS parameters include:
  - Parenchymal nonhomogeneity—the most useful diagnostic marker (4)[A]
  - US inflammatory findings include hypoechoic and hyperechoic bands (4)[A].
  - Real-time sonoelastography (RTS) to quantify tissue rigidity and assess glandular damage (4)[A]

**TREATMENT**
- Treatment is primarily supportive.
- Treat sicca symptoms—dry eyes, dry mouth.
- Avoid medications that may worsen oral dryness (i.e., anticholinergics).
- Promote good oral hygiene.
- Treat systemic manifestations.
- Address fatigue and pain.

**MEDICATION**
- Therapy for sicca symptoms: artificial tears and ocular lubricants (5)[C]
- Topical therapy for dry mouth: liberal sips of water, sugar-free lemon drops, or artificial saliva preparations such as Salivart, Saliment, Xero-Lube, MouthKote
- Immunosuppressive therapy such as hydroxychloroquine can be used for systemic symptoms; however, it has not shown any benefit in relieving refractory sicca symptoms.
- Cevimeline (Evoxac) works by stimulating muscarinic cholinergic receptors to increase salivary gland secretion and may be prescribed for SS-associated xerostomia.
- Dry eyes are graded by severity of symptoms, conjunctival injection and staining, corneal damage, tear quality, and lid involvement. Artificial tears may be used; however, artificial tears with hydroxyethylcellulose or dextran are more viscous and can last longer.
- Acetaminophen or NSAIDs for arthralgias

**First Line**
- Xerostomia: sugar-free lozenges, especially malic acid, artificial saliva; pilocarpine 5 mg PO QID or cevimeline 30 mg PO TID
- Keratoconjunctivitis sicca: artificial tears and ocular lubricants for symptomatic relief, topical cyclosporine (Restasis), or autologous tears

**Second Line**
Xerostomia: Interferon-α lozenges may enhance salivary gland flow.
Keratoconjunctivitis sicca: topical glucocorticoids or topical NSAIDs (Use with caution.)
Immunosuppressive therapy: antimalarials (e.g., hydroxychloroquine) for arthralgias, lymphadenopathies, and skin manifestations; may then consider methotrexate or cyclosporine, which showed subjective improvement but no significant objective improvement
Early studies show improvement in fatigue with rituximab (6)[B].
For life-threatening extraglandular manifestations, cyclophosphamide (PO or IV), mycophenolate mofetil, and azathioprine are often used.

**ISSUES FOR REFERRAL**
- Rheumatology to help manage systemic manifestations or resistant symptoms
- Oral health
- Ophthalmology for grading of severity and management of xerophthalmia

**ADDITIONAL THERAPIES**
- Patients should use vaginal lubricants (e.g., Replens) for vaginal dryness. Vaginal estrogen creams can help in postmenopausal women. Be alert for and treat vaginal yeast infections.
- Xerostomia: small sips of water, good dental care
- Keratoconjunctivitis sicca: Conserve tears with side shields or ski/swim goggles, humidifiers, and moist washcloths.
- Dehydroepiandrosterone (DHEA) does not offer improvement in fatigue and well-being above placebo.

**SURGERY/OTHER PROCEDURES**
Keratoconjunctivitis sicca: If refractory to artificial tears, punctal occlusion is the treatment of choice.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Some studies show acupuncture benefits saliva production and symptoms of xerostomia.
- There is insufficient evidence to determine the effects of electrostimulation devices on dry mouth symptoms or saliva production in patients with SS.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
May be required for extraglandular manifestations, such as cardiopulmonary disease, renal involvement, and CNS manifestations (e.g., optic neuritis, transverse myelitis, vasculitis, or ischemic stroke)

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Frequency of follow-up depends on severity.

**Patient Monitoring**
- Monitor for complications, systemic manifestations, and relief of symptoms.
- Medicolegal pitfalls: Monitor for parotid tumor or lymphoma.

**PATIENT EDUCATION**
In most cases, simple measures are adequate: humidifiers, sips of water, chewing gum, artificial
tears.

**PROGNOSIS**
- Hypocomplementemia is an independent risk factor for premature death.
- Primary SS is associated with increased risks of malignancy, non-Hodgkin lymphoma, and thyroid cancer.

**COMPLICATIONS**
Complications include dental caries, gum disease, dysphagia, salivary gland calculi, keratitis, conjunctivitis, and scarring of the ocular surface.

**REFERENCES**

**CODES**

**ICD10**
- M35.00 Sicca syndrome, unspecified
- M35.02 Sicca syndrome with lung involvement
- M35.09 Sicca syndrome with other organ involvement

**CLINICAL PEARLS**
- Many symptoms of SS can be treated with simple interventions such as artificial tears and sugar-free lozenges.
- Consider lacrimal duct plugs for dry eyes.
- Consider SS in patients with unexplained lung disease and +ANA.
- Patients with primary SS may have an increased incidence of celiac disease.
BASICS

DESCRIPTION

- Obstructive sleep apnea (OSA) is defined as repetitive episodes of cessation of airflow (apnea) through the nose and mouth during sleep due to obstruction at the level of the pharynx.
  - Apneas often terminate with a snort/gasp.
  - Repetitive apneas produce sleep disruption, leading to excessive daytime sleepiness (EDS).
  - Associated with oxygen desaturation and nocturnal hypoxemia
  - Usual course is chronic.

- System(s) affected: cardiovascular; nervous; pulmonary
- Synonym(s): sleep apnea syndrome; nocturnal upper airway occlusion

EPIDEMIOLOGY

Incidence

- Predominant age: middle-age men and women
- Predominant sex: male > female (2:1)

Prevalence

- Up to 15% in men, 5% in women
- Prevalence is higher in obese/hypertensive patients.

ETIOLOGY AND PATHOPHYSIOLOGY

OSA occurs when the naso- or oropharynx collapses passively during inspiration. Anatomic and neuromuscular factors contribute to pharyngeal collapse, which leads to hypoxic arousal.

- Anatomic abnormalities, such as increased soft tissue in the palate, tonsillar hypertrophy, macroglossia, and craniofacial abnormalities, predispose the airway to collapse by decreasing the area of the upper airway or increasing the pressure surrounding the airway.
- During sleep, decreased muscle tone in the naso- or oropharynx contributes to airway obstruction and collapse.
- Upper airway narrowing may be due to the following:
  - Obesity, redundant tissue in the soft palate
  - Enlarged tonsils/uvula
  - Low soft palate
  - Large/posteriorly located tongue
  - Craniofacial abnormalities
  - Neuromuscular disorders
  - Alcohol/sedative use before bedtime

RISK FACTORS

- Obesity (strongest risk factor)
- Age >40 years
- Alcohol/sedative intake before bedtime
- Smoking
Nasal obstruction (due to polyps, rhinitis, or deviated septum)
Anatomic narrowing of nasopharynx (e.g., tonsillar hypertrophy, macroglossia, micrognathia, retrognathia, craniofacial abnormalities)
Acromegaly
Hypothyroidism
Neurologic syndromes (e.g., muscular dystrophy, cerebral palsy)

GENERAL PREVENTION
Weight control and avoidance of alcohol and sedatives at night can help to prevent airway collapse.

COMMONLY ASSOCIATED CONDITIONS

- **Common**
  - Hypertension
  - Obesity
  - Daytime sleepiness
  - Metabolic syndrome
- **Rare**
  - Cardiac arrhythmias
  - Cardiovascular disease
  - Congestive heart failure
  - Pulmonary hypertension
  - Nasal obstructive problems

DIAGNOSIS

**HISTORY**
- Elicit a complete history of daytime and nighttime symptoms. Symptoms can be insidious and may have been present for years.
- **Daytime symptoms**
  - EDS or fatigue (cardinal symptom) (1)
  - Mild symptoms are those that occur during quiet activities (e.g., reading, watching television).
  - More severe symptoms are those that occur during dynamic activities (e.g., work, driving).
  - Tired on morning awakening “nonrestorative sleep”
  - Sore/dry throat
  - Poor concentration, memory problems, irritability, mood changes, behavior problems (in children)
  - Morning headaches
  - Decreased libido
  - Depression
- **Nighttime symptoms**
  - Loud snoring (present in 60% of people with OSA)
  - Snort/gasp that arouses patient from sleep but not usually to full consciousness
  - Disrupted sleep
- Witnessed apneic episodes at night

Screening—the USPSTF found that there is insufficient evidence to screen for OSA in asymptomatic adults or in adults with unrecognized symptoms (2)[A]. The USPSTF found no studies that evaluated the effect of screening for OSA on health outcomes.

PHYSICAL EXAM
- OSA is commonly associated with obesity. It is unlikely to be found in those with normal body weight who do not snore (1).
- Focused head and neck exam
  - Short neck with large circumference
  - Oropharynx
    - Narrowing of the lateral airway wall
    - Tonsillar hypertrophy
    - Macroglossia
    - Micrognathia/retrognathia
    - Soft palate edema
    - Long/thick uvula
    - High, arched hard palate
  - Nasopharynx
    - Deviated nasal septum
    - Poor nasal airflow

DIFFERENTIAL DIAGNOSIS
- Other causes of EDS such as the following:
  - Narcolepsy
  - Idiopathic daytime hypersomnolence
  - Inadequate sleep time
  - Depressive episodes with EDS
  - Periodic limb movements disorder
- Respiratory disorders with nocturnal awakenings such as the following:
  - Asthma
  - Chronic obstructive pulmonary disease
  - Congestive heart failure
- Central sleep apnea (Respiratory effort is absent as compared to OSA where effort is present.)
- Sleep-related choking/laryngospasm
- Gastroesophageal reflux
- Sleep-associated seizures (temporal lobe epilepsy)

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- When clinically indicated
  - Thyroid-stimulating hormone to evaluate hypothyroidism
  - CBC to evaluate anemia and polycythemia, which can indicate nocturnal hypoxemia
  - Fasting glucose in obesity to evaluate for diabetes
  - Rare: arterial blood gases to evaluate daytime hypercapnia
- Cephalometric measurements from lateral head and neck radiographs aid in surgical treatment.
Diagnostic Procedures/Other

- The gold standard for OSA is a full-night, in-laboratory polysomnography (PSG), a nighttime sleep study (1)[A],(3)[B].
  - Demonstrates severity of hypoxemia, sleep disruption, and cardiac arrhythmias associated with OSA and elevated end-tidal CO₂
  - Shows repetitive episodes of cessation/marked reduction in airflow despite continued respiratory efforts
  - Apneic episodes must last at least 10 seconds and occur 10 to 15 times per hour and cause decreased oxygen saturation to be considered clinically significant.
  - Complete PSG is expensive, and health insurance may not cover the cost.
- Multiple sleep latency testing is a diagnostic tool used to measure the time it takes from the start of a daytime nap period to the first signs of sleep (sleep latency). It provides an objective measurement of daytime sleepiness.
- The Apnea-Hypopnea Index (AHI) is defined as the total number of apneas and hypopneas divided by the total sleep time in hours.
  - Mild OSA: AHI = 5 to 15
  - Moderate OSA: AHI = 15 to 30
  - Severe OSA: AHI >30
- Split-night PSG (as compared to a full-night PSG) occurs when patients are diagnosed with OSA within the first part of the night and then they can initiate positive pressure device titration during the second half of the night.
- Drugs that may alter the test results include benzodiazepines and other sedatives that can amplify the severity of apnea seen during the sleep study.
- Early data suggest that home-based diagnosis using portable monitoring devices may be an alternative to laboratory-based PSG if the test is of sufficient duration (4)[B].

TREATMENT

- Lifestyle modification is the most frequently recommended treatment for mild to moderate OSA. This includes weight loss, exercise, and avoidance of alcohol, smoking, and sedatives, especially before bedtime.
- Weight loss—shown to decrease the severity of symptoms in obese patients. Lifestyle modifications should be seen as adjunctive rather than curative therapy (5)[A], and a lack of improvement of symptoms with lifestyle modification should not preclude patients from receiving other therapy such as continuous positive airway pressure (CPAP).
- Position changes—if OSA is present only when supine, keep the patient off his or her back when sleeping (e.g., tennis ball worn on back of nightshirt or using a sleep position trainer).
- Positive airway pressure—the most effective therapy for mild, moderate, or severe OSA is CPAP (6)[A]. Treatment with CPAP uses a mask interface and a flow generator to prevent airway collapse, thus helping to prevent apnea, hypoxia, and sleep disturbance. Compared with inactive controls, CPAP significantly improves both objective (24-hour systolic and diastolic blood pressures) and subjective measures (Epworth Sleepiness Scale) in OSA patients with symptoms of daytime sleepiness. CPAP may also decrease the risk for atherosclerosis as well as improves insulin resistance in nondiabetic patients. Early data show that these benefits may not be seen in patients who do not have symptoms of daytime...
Several types of mask interfaces, including nasal masks, oral masks, and nasal pillows, exist for CPAP therapy. Short-term data suggest that nasal pillows are the preferred interface in almost all patients. In patients with compliance difficulty, a different choice of interface may be appropriate.

Oral appliances to treat OSA are available and often subjectively preferred by patients (mandibular advancement devices vs. tongue retaining devices). Although oral appliances have been shown to improve symptoms compared with inactive controls, they are not as effective for reduction of respiratory disturbances as CPAP over short-term data. Treatment with oral appliances may be considered in patients who fail to comply with CPAP therapy.

**MEDICATION**
Medications are yet to be proven effective in treating OSA. Further studies in this area are needed (7).

**First Line**
Some short-term data found fluticasone nasal spray, mirtazapine, physostigmine, and nasal lubricant of some benefit; longer term studies needed

**ISSUES FOR REFERRAL**
If sleep apnea is suspected, patient should be referred for a sleep study evaluation.

**SURGERY/OTHER PROCEDURES**
Surgical corrections of the upper airway include alteration of the uvula and/or palate such as uvulopalatopharyngoplasty (UPPP), tracheostomy, and craniofacial surgery. Currently, no evidence supports the use of surgery for the treatment of OSA (8)[A].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
On admission, patients should continue to use CPAP/dental devices if they do so at home. They should bring in their own appliance and know their CPAP settings.

**ONGOING CARE**
Lifelong compliance with weight loss or CPAP is necessary for successful OSA treatment.

**DIET**
Overweight and obese patients should be encouraged to lose weight, and all patients must avoid weight gain. Weight loss alone could reduce symptoms of OSA.

**PATIENT EDUCATION**
- Weight loss and avoidance of alcohol and sedatives may reduce OSA symptoms particularly in severe cases.
- Significantly sleepy patients should not drive a motor vehicle/operate dangerous equipment.

**PROGNOSIS**
- EDS is reduced dramatically with appropriate apnea control.
- Lifelong compliance with weight loss or CPAP is necessary for effective treatment of OSA, but long-term adherence is poor.
If untreated, OSA is progressive. Significant morbidity and mortality with OSA usually due to motor vehicle accidents or are secondary to cardiac complications, including arrhythmias, cardiac ischemia, and hypertension; data insufficient on whether identification and treatment changes outcomes.

**COMPLICATIONS**

Untreated OSA may increase the risk for development of hypertension, stroke, myocardial infarction, diabetes, cardiovascular disease, and work-related and driving accidents, but it is unclear that treatment reduces or prevents any of these problems.

**Pediatric Considerations**

- The prevalence of pediatric OSA is 1–2% in children 4 to 5 years of age, and the peak incidence is between 3 and 6 years of age (9).
- Etiology: The most common cause is tonsillar hypertrophy. Additional causes are obesity and craniofacial abnormalities. OSA is also seen in children with neuromuscular diseases, such as cerebral palsy and spinal muscular atrophy, due to abnormal pharyngeal muscle control.
- Signs and symptoms
  - Nighttime: loud snoring, restlessness, and sweating
  - Daytime: hyperactivity and decreased school performance
  - EDS is not a significant symptom.
- Diagnosis: Gold standard is PSG. (PSG may be an even better tool in children due to lessened night-to-night variation. There is a lack of studies showing efficacy of home-based diagnostic studies vs. PSG in children.) Abnormal AHI is different in children: >1 to 2 per hour is abnormal.
- Treatment: Surgery is the first-line treatment in cases due to tonsillar enlargement (reduces symptoms in 70%). Some data suggest improved academic performance if tonsillectomy is performed for OSA. For cases due to obesity/craniofacial abnormalities, patients can use CPAP treatment.

**Geriatric Considerations**

The presence of sleep apnea in the geriatric population may be associated with earlier onset of mild cognitive impairment as well as Alzheimer dementia at an earlier age. The rate of decline of cognitive function may be slowed by the usage of CPAP.

**REFERENCES**

CODES

ICD10
G47.33 Obstructive sleep apnea (adult) (pediatric)

CLINICAL PEARLS

- OSA is characterized by repetitive episodes of apnea often terminating in a snort/gasp.
- Laboratory PSG is the key to diagnosis.
- CPAP is the most effective form of treatment for both mild to moderate and moderate to severe OSA.
- Central sleep apnea may mimic OSA.
BASICS

DESCRIPTION
- Shift work disorder (SWD), classified as a circadian rhythm sleep disorder, is caused by a misalignment between the internal circadian rhythm and the required sleep–wake schedule due to erratic or nighttime shift work (1).
- Diagnostic criteria for SWD require all criteria for circadian rhythm disorder in addition to:
  - Criteria for circadian rhythm disorder:
    - Persistent/recurrent sleep disruption due to either an alteration in the circadian (24-hour) timekeeping system or misalignment between endogenous circadian rhythm and exogenous factors that affect sleep
    - Insomnia/excessive daytime sleepiness or both
    - Impairment in occupational, educational, or social functioning
  - Criteria for SWD:
    - Insomnia/excessive sleepiness, accompanied by reduced sleep time, associated with a recurring work schedule that overlaps with the usual time for sleep
    - Symptoms associated with shift work schedule are present for at least 3 months.
    - Sleep log or actigraphy monitoring (with sleep diaries) for at least 14 days demonstrates disturbed sleep (insomnia) and circadian and sleep-time misalignment.
    - Sleep disturbance is not due to another current sleep disorder, mental disorder, medical disorder, substance use disorder, or medication use.

EPIDEMIOLOGY

Prevalence
- Shift work includes night shifts, evening shifts, or rotating shifts. Approximately 15–25% of the workforce in the United States are shift workers (1).
- SWD has been estimated to affect 10–23% of 22 million American shift workers, with a prevalence estimate of approximately 2–5% of the general population (14% night shift workers and 8% of rotating shift workers) (2).

PATHOPHYSIOLOGY
- Circadian rhythms are present in multiple biologic functions, including body temperature, hormone levels, blood pressure, metabolism, cellular regeneration, sleep–wake cycles, and DNA transcription and translation (1).
- Transcription factors involved in circadian rhythms (the “molecular clock”) control production of many proteins expressed with a periodicity of approximately 24 hours. This molecular clock is self-sustaining and requires a daily reset or it may become out of sync with environmental cues (zeitgebers) (1).
- The most powerful zeitgeber (timekeeper) is light. Light transmitted from the retinohypothalamic tract of the eye to the SCN of the hypothalamus upregulates the production of the “clock gene” (PER) (1).
Periods of darkness cause the SCN to induce melatonin release from the pineal gland, which can also help to reset the molecular clock (1).

A dyssynchrony between the endogenous molecular clock and external cues (most notably light/dark cycles) is responsible for circadian rhythm disorders and can impact both physical and mental health (1).

**RISK FACTORS**
- Shift work, including night shifts, early morning shifts, or rotating shifts
- Younger age and “eveningness” (a.k.a. “night owls”) may protect against the development of SWD (1).

**Genetics**
No genetic predisposition has been described.

**GENERAL PREVENTION**
- Limit rotating shifts.
- Use bright light during shifts.
- Schedule brief (10- to 20-minute) naps during shifts, if possible.

**COMMONLY ASSOCIATED CONDITIONS**
- Shift workers often have impaired immediate free recall, decreased processing speed, and selective attention impairments that may worsen with longer duration of shift work (1).
- Shift workers also have a higher risk of vehicular accidents, job-related injuries, absenteeism, and quality control errors (1).
- SWD has been associated with gastrointestinal (GI) disease, specifically peptic ulcer disease, cardiovascular disease (CVD), ischemic stroke, infertility, mood disorders, and pregnancy complications (1,3).
- There is also a possible increased risk of breast and prostate cancer. The International Agency for Research on Cancer (IARC) has classified shift work involving a circadian disruption as a probable carcinogen (4).

**DIAGNOSIS**
Primarily a clinical diagnosis. There are some useful diagnostic aids.

**HISTORY**
- A careful history is critical. Assess for difficulty falling asleep, staying asleep, or nonrestorative sleep.
- Note the following in particular (5)[C]:
  - Sleep/wake habits
  - Degree of alertness or sleepiness
  - Sleep environment
  - Light exposure before, during, and after the shift
  - Job-related factors: length of shift, number of consecutive shifts, commute after shift
  - Medications and over-the-counter (OTC) stimulants such as caffeine or energy drinks
  - Impact on social and domestic responsibilities (including drowsy driving)
- Evaluate for symptoms of other sleep disorders, which often coexist and can exacerbate SWD such as the following:
– Loud snoring and pauses in breathing during sleep (obstructive sleep apnea [OSA])
– Sudden sleep attacks and leg symptoms (restless legs syndrome [RLS])
– Falling asleep at inappropriate times, drop attacks, and daytime fatigue (narcolepsy)

PHYSICAL EXAM
Evaluate for depression, GI disease, CVD, and potential cancer risk as well as signs of OSA such as obesity, a large neck, and a tight oropharynx (5)[C].

DIFFERENTIAL DIAGNOSIS
● Other primary sleep disorders: OSA, RLS, narcolepsy, and psychophysiologic insomnia
● Other circadian rhythm sleep disorders such as delayed sleep phase disorder or jet lag syndrome. Distinguishing among these can be challenging.

DIAGNOSTIC TESTS & INTERPRETATION
Given possible increased risk; screen for CVD and cancer among shift workers.

Initial Tests (lab, imaging)
Fasting lipid panel, fasting glucose, age-appropriate cancer screenings

Diagnostic Procedures/Other
● A sleep/wake diary recording the patient’s sleep/wake habits, amount of sleep, naps during waking hours, and mood (1 to 2 weeks) (5)[C]
● Actigraphy (a mechanical device, often worn on the arm/leg, to measure movement) serves as a gross measure of time and amount of activity and rest (5)[C].
● Polysomnography measures sleep duration and quality. It is not typically used to diagnose SWD but may help rule out other sleep/wake disorders, such as sleep apnea and narcolepsy (1) [C].
● Other diagnostic tools are available, including the Multiple Sleep Latency Test (MSLT), the Morningness-Eveningness Questionnaire (MEQ), and the Epworth Sleepiness Scale (ESS) (1) [C].

Test Interpretation
Sleep diaries and actigraphy data often reveal:
● Increased sleep latency
● Decreased total sleep time
● Frequent awakenings
● Most people revert to nocturnal sleeping on their days off. Every workweek, they must “start over” to shift circadian rhythms to align with work schedules.

TREATMENT
● The only therapeutic modality recommended by the American Academy of Sleep Medicine is planned (prescribed) sleep schedules (6)[C].
● Other commonly used strategies include sleep hygiene optimization, bright light, melatonin, caffeine, other stimulants, hypnotics, and medication sleep aids (discussed below).

GENERAL MEASURES
● Sleep hygiene: An important first step in approaching the treatment of sleep disorders is proper
sleep hygiene. This includes minimizing exposure to bright light before and during scheduled sleep periods (maintain a dark sleeping space, wear dark sunglasses following work shift, wear an eye mask to sleep), maintain a quiet sleep environment (wear ear plugs to sleep, disconnect phone/doorbell), retrain core body temperature to shifted sleep–wake schedule (maintain cool sleeping quarters), and avoid use of stimulants during second half of work shift (1)[C].

- **Sleep time:** protected time for sleep prior to and following work shifts with strategic naps where possible (5)[C]
- **Work/social/domestic factors:** Treat psychosocial stress, depression; encourage healthy eating habits; limit substance use; increase exercise to at least 30 minutes 5 times per week (not within 2 to 4 hours of bedtime) (5)[C].
- **Work-related interventions:** If possible, reduce number of consecutive shifts (<4) or reduce shift duration (<12 hours), allow adequate time between shifts (>11 hours), move heavy workload outside circadian nadir (04:00 to 07:00) (5)[C].
- **Bright light:** Several studies demonstrate that timed bright light and darkness promote adaptation to night work (7)[C].
- Bright light therapy with conventional light/light boxes (10,000 lux preferable, but >1,000 lux will help) 30 min/day during the night/early morning shift prior to the nadir of the core body temperature rhythm

**MEDICATION**

**Sleep-promoting medications:**
- Melatonin may help shift circadian rhythms and can increase the quality and duration of sleep as well as increase alertness during the work shift.
- Ramelteon (Rozerem), a melatonin receptor agonist, is not FDA-approved for treating SWD but may be helpful in improving daytime sleep (1)[C].
- **Antidepressants:** Doxepin (tricyclic) and trazodone are FDA-approved for the treatment of insomnia. Given at low doses, doxepin and trazodone can improve sleep without residual daytime impairment (1)[C].
- **Intermediate-acting hypnotics** such as zolpidem (Ambien) or eszopiclone (Lunesta) can cause postsleep sedation (1)[C]. Long-term use is discouraged due to potential for tolerance/dependence.
- Suvorexant (Belsomra) is an orexin receptor antagonist approved for the treatment of insomnia.
- **Wakefulness-promoting medications:**
  - Modafinil (Provigil) and armodafinil (Nuvigil) are FDA-approved for excessive sleepiness in patients with SWD and can reduce daytime sleepiness and improve cognitive performance (1)[C].
  - Prophylactic caffeine use immediately prior to work shift and during work shift (5)[C]

**First Line**

Circadian shift/sleep promoting: melatonin 3 mg PO or sublingual, 30 minutes before daytime sleep period. Take only when the patient is home and able to go to bed (1)[C].

**Second Line**

- **Wakefulness promoting:**
  - Modafinil initially 200 mg PO 1 hour prior to work shift
  - Armodafinil 150 mg PO 1 hour prior to work shift; long-acting (12 to 16 hours, depending
on food intake) use judiciously in SWD to impede a patient’s ability to sleep after the shift

- **Sleep promoting:**
  - Nonbenzodiazepine hypnotics:
    - Zolpidem 5 to 10 mg or eszopiclone 1 to 3 mg immediately prior to bed; suvorexant 10 to 20 mg PO 30 minutes prior to bed
  - Antidepressants
    - Doxepin (3 to 6 mg) and trazodone (25 to 150 mg), 1 to 2 hours prior to bed (1)[C]
  - Benzodiazepines: Estazolam, flurazepam, quazepam, temazepam, and triazolam are FDA-approved for the treatment of insomnia. Due to high risk of tolerance/withdrawal, use cautiously for short-term treatment of insomnia (1)[C].
  - In general, hypnotics may improve daytime sleep but do not appear to improve sleep maintenance or nighttime alertness. They may also cause residual sedation during work hours. This may worsen SWD symptoms (1)[C].

**ISSUES FOR REFERRAL**
Refer to a sleep specialist for suspicion of other primary sleep disorders or dependence on hypnotics, alcohol, or stimulants.

**ONGOING CARE**

**PATIENT EDUCATION**
- Discuss sleep hygiene and optimizing the sleep environment.
- Shift workers who need to sleep in the daytime should ensure a cool, dark, and quiet sleep environment.
- Reserve bedroom for sleeping and intimacy only. Remove televisions, cell phones, tablets, and laptop computers from the bedroom.
- When going to sleep, turn clock away from bed and discourage prolonged reading in bed.
- Blackout shades help achieve the proper darkness.

- Sleep Diary: http://www.helpguide.org/life/pdfs/sleep_diary.pdf

CODES

ICD10
G47.26 Circadian rhythm sleep disorder, shift work type

CLINICAL PEARLS

- SWD is associated with shortened and disturbed sleep, increased fatigue, decreased alertness, cognitive decrements, increased injury and accident rates, reproductive problems, and increased cardiovascular and GI disease.
- SWD has been classified as a probable carcinogen (possible association with breast and prostate cancer).
- The first diagnostic step in SWD is to obtain and evaluate an accurate sleep diary.
- Appropriate sleep hygiene is the initial step in treatment.
BASICS

DESCRIPTION
- The senses of smell and taste allow a full appreciation of the flavor and palatability of foods and also serve as a warning system against toxins, polluted air, smoke, and spoiled food.
- Physiologically, the chemical senses aid in normal digestion by triggering GI secretions. Smell/taste dysfunction may have a significant impact on quality of life.
- Loss of smell occurs more frequently than loss of taste, and patients frequently confuse the concepts of flavor loss (as a result of smell impairment) with taste loss (an impaired ability to sense sweet, sour, salty, or bitter).
- Smell depends on the functioning of CN I (olfactory nerve) and CN V (trigeminal nerve).
- Taste depends on the functioning of CNs VII, IX, and X. Because of these multiple pathways, total loss of taste (ageusia) is rare.
- Systems affected: nervous, upper respiratory

EPIDEMIOLOGY

Incidence
There are ~200,000 patient visits a year for smell and taste disturbances.

Prevalence
- Predominant sex: male > female. Men begin to lose their ability to smell earlier in life than women.
- Predominant age: Chemosensory loss is age dependent:
  - Age >80 years: 80% have major olfactory impairment; nearly 50% are anosmic.
  - Ages 65 to 80 years: 60% have major olfactory impairment; nearly 25% are anosmic.
  - Age <65 years: 1–2% have smell impairment.
- Estimated >2 million affected in the United States

ETIOLOGY AND PATHOPHYSIOLOGY

- Smell and/or taste disturbances:
  - Nutritional factors (e.g., malnutrition, vitamin deficiencies, liver disease, pernicious anemia)
  - Endocrine disorders (e.g., thyroid disease, diabetes mellitus, renal disease)
  - Head trauma
  - Migraine headache (e.g., gustatory aura, olfactory aura)
  - Sjögren syndrome
  - Toxic chemical exposure
  - Industrial agent exposure
  - Aging
  - Medications (see next column)
  - Neurodegenerative diseases (e.g., multiple sclerosis, Alzheimer disease, cerebrovascular accident, Parkinson disease)
  - Infections (e.g., upper respiratory infection [URI], oral and perioral infections, candidiasis, coxsackievirus, AIDS, viral hepatitis, herpes simplex virus)
Possible causes of smell disturbance:
- Nasal and sinus disease (e.g., allergies, rhinitis, rhinorrhea, URI)
- Cigarette smoking
- Cocaine abuse (intranasal)
- Hemodialysis
- Radiation treatment of head and neck
- Congenital conditions
- Neoplasm (e.g., brain tumor, nasal polyps, intranasal tumor)
- Systemic lupus erythematosus (SLE)
- Bell palsy
- Oral/perioral skin lesion
- Damage to CN I/V
- Possible association with psychosis and schizophrenia

Possible causes of taste loss:
- Oral appliances
- Dental procedures
- Intraoral abscess
- Gingivitis
- Damage to CN VI, IX, or X
- Stroke (especially frontal lobe)

Selected medications that reportedly alter smell and taste:
- Antibiotics: amikacin, ampicillin, azithromycin, ciprofloxacin, clarithromycin, doxycycline, griseofulvin, metronidazole, ofloxacin, tetracycline, terbinafine, β-lactamase inhibitors
- Anticonvulsants: carbamazepine, phenytoin
- Antidepressants: amitriptyline, doxepin, imipramine, nortriptyline
- Antihistamines and decongestants: zinc-based cold remedies (Zicam)
- Antihypertensives and cardiac medications: acetazolamide, amiloride, captopril, diltiazem, hydrochlorothiazide, nifedipine, propranolol, spironolactone
- Anti-inflammatory agents: auranofin, gold, penicillamine
- Antimanic drugs: lithium
- Antineoplastics: cisplatin, doxorubicin, methotrexate, vincristine
- Antiparkinsonian agents: levodopa, carbidopa
- Antiseptic: chlorhexidine
- Antithyroid agents: methimazole, propylthiouracil
- Lipid-lowering agents: statins

Genetics
May be related to underlying genetically associated diseases (Kallmann syndrome, Alzheimer disease, and other neurodegenerative disorders, migraine syndromes, rheumatologic conditions, endocrine disorders)

RISK FACTORS
- Age >65 years
- Poor nutritional status
- Smoking tobacco products

GENERAL PREVENTION
Eat a well-balanced diet, with appropriate vitamins and minerals.  
Maintain good oral and nasal health, with routine visits to the dentist.  
Do not smoke tobacco products.  
Avoid noxious chemical exposures/unnecessary radiation.

**Geriatric Considerations**  
- Elders are at particular risk of eating spoiled food or inadvertently being exposed to natural gas leaks owing to anosmia from aging.  
- Anosmia also may be an early sign of degenerative disorders and has been shown to predict increased 5-year mortality (1)[B]. In a separate study, healthy elders (average age 76) with loss of smell had 46% increased mortality at 10 years, 30% increased mortality at 13 years. In an analysis of cause of mortality, only 30% of the increased mortality could be ascribed to neurodegenerative causes, and only 6% to weight loss. The mechanisms of increased mortality for the remaining 64% were not obvious from the data (2)[B].

**Pediatric Considerations**  
- Smell and taste disorders are uncommon in children in developed countries.  
- In developing countries with poor nutrition (particularly zinc depletion), smell and taste disorders may occur.  
- Delayed puberty in association with anosmia (± midline craniofacial abnormalities, deafness, or renal abnormalities) suggests the possibility of Kallmann syndrome (hypogonadotropic hypogonadism).

**Pregnancy Considerations**  
- Pregnancy is an uncommon cause of smell and taste loss or disturbances.  
- Many women report increased sensitivity to odors during pregnancy as well as an increased dislike for bitterness and a preference for salty substances.

**COMMONLY ASSOCIATED CONDITIONS**  
URI, allergic rhinitis, dental abscesses

**DIAGNOSIS**  
Smell and taste disturbances are symptoms; it is essential to look for possible underlying causes.

**HISTORY**  
- Symptoms of URI, environmental allergies  
- Oral pain, other dental problems  
- Cognitive/memory difficulties  
- Current medications  
- Nutritional status, ovolactovegetarian  
- Weight loss or gain  
- Frequent infections (impaired immunity)  
- Worsening of underlying medical illness  
- Increased use of salt and/or sugar to increase taste of food  
- Neurodegenerative disease

**PHYSICAL EXAM**
Thorough HEENT exam

**DIFFERENTIAL DIAGNOSIS**
- Epilepsy (gustatory aura)
- Epilepsy (olfactory aura)
- Memory impairment
- Psychiatric conditions

**DIAGNOSTIC TESTS & INTERPRETATION**

Initial Tests (lab, imaging)
Consider (Not all patients require all tests.)
- CBC
- Liver function tests
- Blood glucose
- Creatinine
- Vitamin B₁₂ level
- Thyroid-stimulating hormone (TSH)
- Serum IgE
- CT scanning is the most useful and cost-effective technique for assessing sinonasal disorders and is superior to an MRI in evaluating bony structures and airway patency. Coronal CT scans are particularly valuable in assessing paranasal anatomy (3)[B].

Follow-Up Tests & Special Considerations
Diagnosis of smell and taste disturbances is usually possible through history; however, the following tests can be used to confirm:
- Olfactory tests
  - Smell identification test: evaluates the ability to identify 40 microencapsulated scratch-and-sniff odorants (4)[B]
  - Brief smell identification test (5)[B]
  - Taste tests (more difficult because no convenient standardized tests are presently available): Solutions containing sucrose (sweet), sodium chloride (salty), quinine (bitter), and citric acid (sour) are helpful.
  - An MRI is useful in defining soft tissue disease; therefore, a coronal MRI is the technique of choice to image the olfactory bulbs, tracts, and cortical parenchyma; possible placement of an accessory coil (TMJ) over the nose to assist in imaging

**TREATMENT**

**GENERAL MEASURES**
- Appropriate treatment for underlying cause
- Quit smoking (6)[B].
- Treatment of underlying nasal congestion with nasal decongestants and/or nasal/oral steroids (7)[B]
- Surgical correction of nasal blockage/nasal polyps
- Some drug-related smell or taste loss or dysgeusias can be reversed with cessation of the offending medication, but it may take many months.
Stop repeated oral trauma (e.g., appliances, tongue-biting behaviors).
Proper nutritional and dietary assessment (3)[C]
Formal dental evaluation

MEDICATION
- Treat underlying causes as appropriate. Idiopathic cases will often resolve spontaneously.
- Consider trial of corticosteroids topically (e.g., fluticasone nasal spray daily to BID) and/or systemically (e.g., oral prednisone 60 mg daily for 5 to 7 days) (7)[B].
- Zinc and vitamins (A, B complex) when deficiency is suspected

ISSUES FOR REFERRAL
- Consider referral to an otolaryngologist or neurologist for persistent cases.
- Referral to a subspecialist at a regional smell and taste center when complex etiologies are suspected

SURGERY/OTHER PROCEDURES
If needed for treatment of underlying cause

ONGOING CARE

DIET
- Weight gain/loss is possible because the patient may reject food or may switch to calorie-rich foods that are still palatable.
- Ensure a nutritionally balanced diet with appropriate levels of nutrients, vitamins, and essential minerals.

PATIENT EDUCATION
- Caution patients not to overindulge as compensation for the bland taste of food. For example, patients with diabetes may need help in avoiding excessive sugar intake as an inappropriate way of improving food taste.
- Patients with chemosensory impairments should use measuring devices when cooking and should not cook by taste.
- Optimizing food texture, aroma, temperature, and color may improve the overall food experience when taste is limited.
- Patients with permanent smell dysfunction must develop adaptive strategies for dealing with hygiene, appetite, safety, and health.
- Natural gas and smoke detectors are essential; check for proper function frequently.
- Check food expiration dates frequently; discard old food.

PROGNOSIS
- In general, the olfactory system regenerates poorly after a head injury. Most patients who recover smell function following head trauma do so within 12 weeks of injury.
- Patients who quit smoking typically recover improved olfactory function and flavor sensation.
- Many taste disorders (dysgeusias) resolve spontaneously within a few years of onset.
- Phantosmias that are flow dependent may respond to surgical ablation of olfactory mucosa.
- Conditions such as radiation-induced xerostomia and Bell palsy generally improve over time.
COMPLICATIONS
- Permanent loss of ability to smell/taste
- Psychiatric issues with dysgeusias and phantosmia

REFERENCES

ADDITIONAL READING

CODES
ICD10
- R43.9 Unspecified disturbances of smell and taste
- R43.1 Parosmia
- R43.2 Parageusia

CLINICAL PEARLS
- Smell disorders are often mistaken as decreased taste by patients.
- Most temporary smell loss is due to nasal passage obstruction.
- Actual taste disorders are often related to dental problems or medication side effects.
- Gradual smell loss is very common in the elderly; extensive workup in this population may not be indicated if no associated signs/symptoms are present but may be predictive of 5–13 year mortality.
SOMATIC SYMPTOM (SOMATIZATION) DISORDER
William G. Elder, PhD

BASICS

DESCRIPTION
- Somatic symptom disorders (SSD) are a pattern of one or more somatic symptoms recurring or persisting for >6 months that are distressing or result in significant disruption of daily life.
- Designation of a symptom as somatic means that it appears to be a physical problem or complaint yet is medically unexplained.
- Conceptualization and diagnostic criteria for somatic symptom presentations were significantly modified with the advent of DSM-5. SSD is similar in many aspects to the former somatization disorder, which required presentation with multiple physical complaints. No longer based on symptoms counts; current diagnosis is based on the way the patient presents and perceives his or her symptoms.
- SSD now includes most presentations that would formerly be considered hypochondriasis. Hypochondriasis has been replaced by illness anxiety disorder, which is diagnosed when the patient presents with significant preoccupation with having a serious illness in the absence of illness-related somatic complaints.
- Somatization increases disability independent of comorbidity, and individuals with SSD have health-related functioning that is 2 standard deviations below the mean.
- Symptoms may be specific (e.g., localized pain) or relatively nonspecific (e.g., fatigue).
- Symptoms sometimes may represent normal bodily sensations or discomfort that does not signify serious disease.
- Suffering is authentic. Symptoms are not intentionally produced or feigned.
- SSDs are sometimes referred to as “functional disorders” to denote their nonphysical basis.

EPIDEMIOLOGY

Incidence
- Usually, first symptoms appear in adolescence.
- Predominant sex: female > male (10:1)
- Type and frequency of somatic complaints may differ among cultures, so symptom reviews should be adjusted based on culture; more frequent in cultures without Western/empirical explanatory models

Prevalence
- Expected 2% among women and <0.2% among men
- Somatization seen in up to 29% of patients presenting to primary care offices
- Somatic concerns may increase, but other features of the presentation decrease such that prevalence declines after age 65 years.

ETIOLOGY AND PATHOPHYSIOLOGY
Patients with SSD demonstrate different patterns of heart rate variability. Although this cannot be used to clinically differentiate, it does point to the differences in psychophysiology of SSD. Also, not to be used clinically, patients with SSD display differences in brain functional connectivity, with the possibility that deficits in attention distort perception of external stimuli,
affecting regulation of externally responsive body functioning (1)[C].

**Genetics**
Consanguinity studies and single nucleotide polymorphism genotyping indicate that both genetic and environmental factors contribute to the risk of SSD.

**RISK FACTORS**
- Child abuse, particularly sexual abuse, has been shown to be a risk factor for somatization.
- Symptoms begin or worsen after losses (e.g., job, close relative, or friend).
- Greater intensity of symptoms often occurs with stress.

**COMMONLY ASSOCIATED CONDITIONS**
Comorbid with other psychiatric conditions is yet to be determined but is likely to be 20–50% with anxiety, depression, or personality disorders.

**DIAGNOSIS**
- Determining that a somatic symptom is medically unexplained is unreliable, and it is inappropriate to diagnose a mental disorder solely because a medical diagnosis is not demonstrated. Rely on symptoms and presentation rather than ruling out medical causes in making the SSD diagnosis.
- Illness anxiety and somatic distress are independent but often co-occur.

**HISTORY**
- One or more somatic complaints, with sometimes a grossly positive review of symptoms
- SSD involves patient unrealistic thoughts, feelings, or behaviors associated with symptoms or associated health concerns manifested by at least one of the following:
  - Disproportionate and persistent thoughts about the seriousness of the symptoms
  - Persistent high level of anxiety about health or symptoms
  - Excessive time or energy devoted to symptoms or health concerns
- Diagnoses no longer rely on symptom counts, but common symptoms include:
  - Pain symptoms related to different sites such as head, abdomen, back, joints, extremities, chest, or rectum, or related to body functions such as menstruation, sexual intercourse, or urination
  - GI symptoms such as nausea, bloating, vomiting (not during pregnancy), diarrhea, intolerance of several foods
  - Sexual symptoms such as indifference to sex, difficulties with erection or ejaculation, irregular menses, excessive menstrual bleeding, or vomiting throughout all 9 months of pregnancy
  - Pseudoneurologic symptoms such as impaired balance or coordination, weak or paralyzed muscles, lump in throat or trouble swallowing, loss of voice, retention of urine, hallucinations, numbness (to touch or pain), double vision, blindness, deafness, seizures, amnesia or other dissociative symptoms, loss of consciousness (other than with fainting); none of these is limited to pain.
- Patients with SSD frequently use alternative treatments, which should be explored for their effects on health and physical functioning.

**PHYSICAL EXAM**
Physical exam remarkable for absence of objective findings to explain the many subjective complaints

DIFFERENTIAL DIAGNOSIS

- Other psychiatric illnesses must be ruled out:
  - Depressive disorders
  - Anxiety disorders
  - Schizophrenia
  - Other somatic disorders: illness anxiety disorder, conversion disorder
  - Factitious disorder
  - Body dysmorphic disorder
- Malingering
- General medical conditions, with vague, multiple, confusing symptoms, must be ruled out:
  - Systemic lupus erythematous
  - Hyperparathyroidism
  - Hyper- or hypothyroidism
  - Lyme disease
  - Porphyria

DIAGNOSTIC TESTS & INTERPRETATION

Several screening tools are available that help to identify symptoms as somatic:
- Patient Health Questionnaire (PHQ)-15 (screens and monitors symptoms)
- Minnesota Multiphasic Personality Inventory (MMPI) (identifies somatization)

Initial Tests (lab, imaging)

- Laboratory test results do not support the subjective complaints.
- Imaging studies do not support the subjective complaints.

Test Interpretation

None are identified.

TREATMENT

GENERAL MEASURES

- The goal of treatment is to help the person learn to control the symptoms.
- It is not helpful to tell patients that their symptoms are imaginary. Enhanced or structured care as follows can be as effective as psychological interventions in adults (2)[A].
- The involvement of a single provider is important because a history of seeking medical attention and “doctor shopping” is common.
- Patients usually receive the most benefit from primary care providers who accept the limitations of treatment, listen to their patient’s concerns, and provide reassurance.
- A supportive relationship with a sympathetic health care provider is the most important aspect of treatment:
  - Regular scheduled appointments should be maintained to review symptoms and the person’s coping mechanisms (at least 15 minutes once a month).
  - Acknowledge and explain test results.
- Antidepressant or antianxiety medication and referral to a support group or mental health
provider can help patients who are willing to participate in their treatment.

MEDICATION
- Fluoxetine has been shown to have efficacy with illness anxiety disorder (formerly hypochondriasis), although >50% of those patients did not respond to the medication (3)[B].
- Antidepressants (e.g., SSRIs) help to treat comorbid depression and anxiety (4)[C].

ISSUES FOR REFERRAL
- Discourage referrals to specialists for further investigation of somatic complaints.
- Referrals to support groups or to a mental health provider may be helpful.

ADDITIONAL THERAPIES
- Treatments have not been evaluated for this recently reformulated disorder. However, there are numerous studies with positive outcomes for child and adult patients with various forms of somatization or medically unexplained symptoms.
- Treatment typically includes long-term therapy, which has been shown to decrease the severity of symptoms.
- Individual or group cognitive-behavioral therapy addressing health anxiety, health beliefs, and health behaviors has been shown to be the most efficacious treatment for somatoform disorders. Cognitive processes modified in therapy include patient tendencies to ruminate and catastrophize (5)[A].
- For children, psychological interventions reduce symptom numbers and severity, disability, and school absence (6)[A].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patients should have regularly scheduled follow-up with a primary care doctor, psychiatrist, and/or therapist.

PATIENT EDUCATION
Encourage interventions that decrease stressful elements of the patient’s life:
- Psychoeducational advice
- Increase in exercise
- Pleasurable private time

PROGNOSIS
- Chronic course, fluctuating in severity
- Full remission is rare.
- Individuals with this disorder do not experience any significant difference in mortality rate or significant physical illness.
- Patients with this diagnosis do experience substantially greater functional disability and role impairment than nonsomatizing patients.

COMPLICATIONS
- May result from invasive testing and from multiple evaluations that are performed while looking for the cause of the symptoms
A dependency on pain relievers or sedatives may develop.

REFERENCES

ADDITIONAL READING

CODES

ICD10

- F45.9 Somatoform disorder, unspecified
- F45.20 Hypochondriacal disorder, unspecified
- F45.22 Body dysmorphic disorder

CLINICAL PEARLS

- Diagnosis is based on a pattern of symptoms rather than an absence of medical explanation.
- A clue is accumulation of several diagnoses with >13 letters (e.g., chronic fatigue syndrome, fibromyalgia syndrome, reflex sympathetic dystrophy, temporomandibular joint syndrome, carpal tunnel syndrome, mitral valve prolapse).
- Inability of more than three physicians to make a meaningful diagnosis suggests somatization.
- Acknowledge the patient’s pain, suffering, and disability.
- Do not tell patients the symptoms are “all in their head.”
- Emphasize that this is not a rare disorder.
- Discuss the limitations of treatment while providing reassurance that there are interventions
that will lessen suffering and reduce symptoms.
SPINAL STENOSIS
N. Wilson Holland, MD, FACP • Birju B. Patel, MD, FACP, AGSF

BASICS

DESCRIPTION
Narrowing of the spinal canal and foramen:
- Spondylosis or degenerative arthritis is the most common cause of spinal stenosis, resulting from compression of the spinal cord by disc degeneration, facet arthropathy, osteophyte formation, and ligamentum flavum hypertrophy.
- The L4–L5 level is most commonly involved.

EPIDEMIOLOGY
The prevalence of spinal stenosis increases with age due to “wear and tear” on the normal spine.

Incidence
Symptomatic spinal stenosis affects up to 8% of the general population.

Prevalence
- The prevalence of spinal stenosis is high if assessed solely by imaging in elderly patients. Not all patients with radiographic spinal stenosis are symptomatic. The degree of radiographic stenosis does not always correlate with patient symptoms. Lumbar magnetic resonance imaging (MRI) shows significant abnormalities in 57% of patients >60 years.
- Predominant age: Symptoms develop in 5th to 6th decades (congenital stenosis is symptomatic earlier).

ETIOLOGY AND PATHOPHYSIOLOGY
- Spinal stenosis can result from congenital or acquired causes. Degenerative spondylosis is most common.
- Disc dehydration leads to loss of height with bulging of the disc annulus and ligamentum flavum into the spinal canal, increasing facet joint loading.
- Facet loading leads to reactive sclerosis and osteophytic bone growth, further compressing spinal canal, and foraminal elements.
- Other causes of acquired spinal stenosis include:
  - Trauma
  - Neoplasms
  - Neural cysts and lipomas
  - Postoperative changes
  - Rheumatoid arthritis
  - Diffuse idiopathic skeletal hyperostosis
  - Ankylosing spondylitis
  - Metabolic/endocrine causes: osteoporosis, renal osteodystrophy, and Paget disease

Genetics
No definitive genetic links

RISK FACTORS
Increasing age and degenerative spinal disease

**GENERAL PREVENTION**

There is no proven prevention for spinal stenosis. Symptoms can be alleviated with flexion at the waist:

- Leaning forward while walking
- Pushing a shopping cart
- Lying in flexed position
- Sitting
- Avoiding provocative maneuvers (back extension, ambulating long distances without resting)

**DIAGNOSIS**

**HISTORY**

- Helps distinguish spinal stenosis from other causes of back pain and peripheral vascular disease
  - Insidious onset and slow progression are typical; discomfort with standing, paresthesias, and weakness (often bilateral) (1)
  - Symptoms worsen with extension (prolonged standing, walking downhill or downstairs).
  - Symptoms improve with flexion (sitting, leaning forward while walking, walking uphill or upstairs, lying in a flexed position).
- Neurogenic claudication (i.e., pain, tightness, numbness, and subjective weakness of lower extremities) may mimic vascular claudication.

**PHYSICAL EXAM**

Neurologic exam may be normal. Key exam areas:

- Examine gait (rule out cervical myelopathy or intracranial pathology).
- Loss of lumbar lordosis
- Evaluate range of motion of lumbar spine.
- Pain with extension of the lumbar spine is typical.
- Straight leg raise test may be positive if nerve root entrapment is present.
- Muscle weakness when apparent usually involves L4–L5 nerve roots (demonstrated by weakness in great toe extension and hip abduction) and less commonly S1 nerve roots (demonstrated by hip extension weakness).
- About half of patients with symptomatic stenosis have a reduced or absent Achilles reflex. Some have reduced or absent patellar reflex.

**DIFFERENTIAL DIAGNOSIS**

- Vascular claudication. Symptoms of vascular claudication do not improve with leaning forward and usually abate with standing or rest.
- Disc herniation
- Cervical myelopathy

**DIAGNOSTIC TESTS & INTERPRETATION**

Generally, a clinical diagnosis. Imaging (MRI is best) is used to stage severity and plan treatment.
**Initial Tests (lab, imaging)**
- Complete blood count, erythrocyte sedimentation rate, C-reactive protein (if considering infection or malignancy)
- New back pain lasting >2 weeks or back pain accompanied by neurologic findings in patients >50 years generally warrants neuroimaging.
- MRI is the modality of choice.
- CT myelography is an alternative to MRI but is invasive and has higher risk of complications.
- Plain radiography helps exclude other causes of new back pain (e.g., malignant lytic lesions, vertebral compression fractures) but does not reveal the underlying pathology.
- Radiologic abnormalities in general do not correlate with the clinical severity.

**Diagnostic Procedures/Other**
Surgical decompression is definitive for patients who are symptomatic after nonoperative treatment:
- Spinal stenosis generally does not lead to neurologic damage.
- Surgery may be required for pain relief to increase mobility and improve quality of life.

**Test Interpretation**
Common radiographic findings include decreased disc height, facet hypertrophy, and spinal canal and/or foraminal narrowing.

**TREATMENT**

- In general, nonoperative interventions are preferred in the absence of progressive or debilitating neurologic symptoms:
  - Physical therapy, exercise, weight management, medications, and epidural steroid injections are options. There is insufficient evidence to definitively guide clinical practice.
  - Patients should understand that the benefits of surgery may diminish over time.
  - Rule out other neuropathies and peripheral vascular disease.
- Spinal decompression and physical therapy yield similar effects (2)[A].

**MEDICATION**

**First Line**
Nonsteroidal anti-inflammatory drugs: Consider potential for gastrointestinal (GI) side effects, fluid retention, and renal failure.

**Second Line**
- Tramadol—currently a schedule IV-controlled substance; has the potential to cause confusion, dizziness, lower seizure threshold, and increase fall risk in the elderly; should be used with caution
- The available evidence does not support the routine use of epidural steroid injections. A randomized study comparing injections of glucocorticoids plus lidocaine versus lidocaine alone showed no significance in symptoms at 6 weeks in these two groups (3)[B].
- Use opioids sparingly and only when other treatments have failed to control severe pain.

**Geriatric Considerations**
- Anti-inflammatory medications should be used with caution in the elderly due to the risks of
GI bleeding, fluid retention, renal failure, and cardiovascular risks.
• Side effects of opioids include constipation, confusion, urinary retention, drowsiness, nausea, vomiting, and the potential for dependence and abuse.
• >10% of elderly lack Achilles reflexes.

ISSUES FOR REFERRAL
Patients in unremitting pain or with a neurologic deficit should see a neurosurgeon.

ADDITIONAL THERAPIES
• Patients with spinal stenosis are typically able to ride a bicycle (leaning forward tends to relieve symptoms).
• Aquatic therapy (helpful for muscle training and general conditioning)
• Strengthening of abdominal and back muscles
• Gait training
• Although a brace or corset may help in the short term, use is not recommended for prolonged periods due to development of paraspinal muscle weakness.
• Encourage physical activity to prevent deconditioning.

SURGERY/OTHER PROCEDURES
• Surgery is indicated when symptoms persist despite conservative measures.
• Age alone should not be an exclusion factor for surgical intervention. Cognitive impairment, multiple comorbidities, and osteoporosis may increase the risk of perioperative complications in the elderly.
• Interspinous process spacers (IPS) may be used for moderate disease. Advantages of this procedure include being less invasive and preserving more spinal mobility as compared to laminectomy (4)[B].
• Laminectomy and partial facetectomy is used for severe disease or if spacers (IPS) are no longer helpful.
• Fusion is no longer a standard of care; patients with lumbar spinal stenosis decompression surgery plus fusion surgery did not result in better clinical outcomes at 2 years and 5 years than did decompression surgery alone (5)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
• Admission criteria/initial stabilization: acute or progressive neurologic deficit
• Discharge criteria: improved pain or after neurologic deficit has been addressed

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
• Follow up based on progression of symptoms.
• No limitations to activity; patients may be as active as tolerated. Exercise should be encouraged.

Patient Monitoring
Patients are monitored for improvement of symptoms and development of any complications.

DIET
Optimize nutrition for weight management.

PATIENT EDUCATION
- Activity as tolerated, if no other pathology is present (e.g., fractures)
- Patients should present for care if they develop progressive motor weakness and/or bladder/bowel dysfunction.
- Patients should know the natural history of the condition and how best to relieve symptoms.

PROGNOSIS
- Spinal stenosis is generally benign, but the pain can lead to limitation in activities of daily living and progressive disability.
- Surgery usually improves pain and symptoms in patients who fail nonoperative treatment.
- Surgical outcomes are similar in terms of pain relief and functional improvement for patients of all ages.

COMPLICATIONS
- Severe spinal stenosis can lead to bowel and/or bladder dysfunction.
- Surgical complications include infection, neurologic injury, chronic pain, and disability.

REFERENCES

SEE ALSO
Algorithm: Low Back Pain, Acute

CODES
ICD10
- M48.00 Spinal stenosis, site unspecified
- M48.06 Spinal stenosis, lumbar region
- M48.04 Spinal stenosis, thoracic region

CLINICAL PEARLS
- Spinal stenosis typically presents as neurogenic claudication (pain, tightness, numbness, and
subjective weakness of lower extremities), which can mimic vascular claudication.

- Flexion of the spine generally relieves symptoms associated with spinal stenosis.
- Spinal extension (prolonged standing, walking downhill, and walking downstairs) can worsen symptoms of spinal stenosis.
- Consider urgent surgery for patients with cauda equina/conus medullaris syndrome or progressive bladder dysfunction. Other patients with lumbar spinal stenosis typically do well with initial conservative management.
- For patients with lumbar spinal stenosis who do not have fixed or progressive neurologic deficits, should be managed with conservative treatment. Physical therapy and/or oral pain medication are often used, although their efficacy has not been well evaluated.
SPRAIN, ANKLE
Shane L. Larson, MD  •  Brandon J. Moore, BS, MPAS

BASICS

DESCRIPTION

The most common cause of ankle injury comprising a significant proportion of sports injuries:

- Types of ankle sprains: lateral, medial, and syndesmotic (or high ankle sprain)
  - Lateral ankle sprains are the most common, accounting for up to 89% of all ankle sprains (1):
    - In lateral ankle sprains, the anterior talofibular ligament (ATFL) is most likely to be injured.
    - The calcaneofibular ligament (CFL) is the second most likely ligament to be injured.
    - The posterior talofibular ligament (PTFL) is the least likely to be injured.
  - Medial ankle sprains (5–10%) result from an injury to the deltoid ligament.
  - Syndesmotic (“high ankle sprain”) injuries account for 5–10% of ankle sprains.
    - The syndesmosis between the distal tibia and distal fibula bones consists of the anterior, posterior, and transverse tibiofibular ligaments; the interosseous ligament; and interosseous membrane.

- Ankle sprains are classified according to the degree of ligamentous disruption:
  - Grade I: mild stretching of a ligament with possible microscopic tears
  - Grade II: incomplete tear of a ligament
  - Grade III: complete ligament tear

Geriatric Considerations

Increased risk of fracture in patients with preexisting bone weakness (osteoporosis/osteopenia)

Pediatric Considerations

- Increased risk of physeal injuries instead of ligament sprain because ligaments have greater tensile strength than physis
- Inversion ankle injuries in children may have a concomitant fibular physeal injury (Salter-Harris type I or higher fracture).
- Consider tarsal coalition with recurrent ankle sprains.

EPIDEMIOLOGY

Incidence

- Ankle sprains are more common in childhood and adolescents, particularly in active individuals (2).
- 1/2 of all ankle sprains are sports related; highest incidence in indoor/court sports (basketball, volleyball, tennis), followed by football and soccer (3)
- Most common sports injury
- More common in males age <30 years and females >30 years old

Prevalence

- 25% of sports injuries in the United States
- 75% of all ankle injuries are sprains.
ETIOLOGY AND PATHOPHYSIOLOGY
- Lateral ankle sprains result from an inversion force with the ankle in plantar flexion.
- Medial ankle sprains are due to forced eversion while the foot is in dorsiflexion.
- Syndesmotic sprains result from eversion stress/extreme dorsiflexion along with internal rotation of tibia.

RISK FACTORS
- The greatest risk factor is a prior history of an ankle sprain (3–34% recurrence rate).
- Postural instability, gait alterations
- Joint laxity and decreased proprioception are not risk factors.

GENERAL PREVENTION
- Improve overall physical conditioning:
  - Training in agility and flexibility
  - Single-leg balancing
  - Proprioceptive training
- Taping and bracing may help prevent primary injury in selected sports (i.e., volleyball, basketball, football) or reinjury (4). Taping and bracing do not reduce sprain severity.
  - Weight loss may help in overweight patients (4)[A].

COMMONLY ASSOCIATED CONDITIONS
- Contusions
- Fractures
  - Fibular head fracture/dislocation (Maisonneuve)
  - Fracture of the base of the 5th metatarsal
  - Distal fibula physeal fracture (includes Salter-Harris fractures in pediatric patients; most common type of pediatric ankle fracture)

DIAGNOSIS

HISTORY
- Elicit specific mechanism of injury (inversion vs. eversion)
- Popping/snapping sensation during the injury
- Previous history of ankle injuries
- Ability to ambulate immediately after the injury
- Rapid onset of pain, swelling, or ecchymosis
- Location of pain (lateral/medial)
- Difficulty bearing weight
- Past medical history of systemic disorders

PHYSICAL EXAM
- Timing: Initial assessment for laxity may be difficult due to pain, swelling, and muscle spasm. Repeating exam ~5 days after injury often improves sensitivity.
- Compare to uninjured ankle for swelling, ecchymosis, weakness, and laxity.
- Neurovascular exam
- Palpate ATFL, CFL, PTFL, and deltoid ligament for tenderness.
- Palpate lateral and medial malleolus, base of 5th metatarsal, navicular, and entire fibula.
– High ankle sprain associated with fracture of proximal fibula

● Grade I sprain: mild swelling and pain; no laxity; able to bear weight/ambulate without pain

● Grade II sprain: moderate swelling and pain; mild laxity with firm end point noted; weight-bearing/ambulation painful

● Grade III sprain: severe swelling, pain, and bruising; laxity with no end point; significant instability and loss of function/motion; unable to bear weight/ambulate
  – Swelling less sensitive for grade of tear in pediatric patient

● Special tests:
  – Anterior drawer test to check for ATFL laxity
  – Talar tilt test to check laxity in CFL (with inversion) or deltoid ligament (eversion)
  – Squeeze test: Compress tibia and fibula midcalf to check for syndesmotic injury; sensitivity 30%, specificity 93.5%
  – Dorsiflexion/external rotation test: Positive test is pain at syndesmosis with rotation; sensitivity 20%, specificity 85%

Differential Diagnosis

● Tendon injury
  – Tendinopathy/tendon tear

● Fracture and/or dislocation of the ankle/foot

● Hindfoot/midfoot injuries

● Nerve injury

● Contusion

Diagnostic Tests & Interpretation

Initial Tests (lab, imaging)

● Ottawa Ankle Rules (nearly 100% sensitive, 30–50% specific) determine need for radiographs to rule out ankle fractures (patient must be 18 to 55 years; certain patients, e.g., diabetics with diminished sensation, may still need radiographs):
  – Pain in malleolar zone
  – Inability to bear weight (walk ≥4 steps) immediately and in the exam room
  – Bony tenderness at tip/posterior edge of the lateral/medial malleolus
  – Reported pain in the midfoot zone AND pain with palpation of navicular
  – Pain on palpation at the base of 5th metatarsal
  – Although Ottawa rules are highly sensitive, they should not overrule clinical judgment.

● If radiographs are indicated, obtain anteroposterior, lateral, and mortise views of the ankle.
  – Small avulsion fractures are associated with grade III sprains.

● Consider CT if radiographs are negative but occult fracture is suspected clinically.

● MRI is the gold standard for soft tissue imaging but is expensive and rarely necessary.
  – Syndesmotic ankle sprains: MRI is more sensitive.

● US is a good second-line imaging option with sensitivity comparable to MRI with experienced sonographers and providers.

Follow-Up Tests & Special Considerations

If patient’s condition does not improve in 6 to 8 weeks, consider CT, MRI, or US. Failure to resolve could indicate an injury such as a fracture or osteochondral lesion of the talus.
TREATMENT

GENERAL MEASURES

- Most grade I, II, and III lateral ankle sprains can be managed conservatively.
- Conservative therapy: PRICE (protection, relative rest, ice, compression, elevation) (4)[A]
- Protection/compression: For grade I/II sprains, lace-up bracing is superior to air-filled/gel-filled ankle brace, which is superior to elastic bandage/taping to provide support and decrease swelling.
  - Note: The combination of air-filled brace and compression wrap is superior to each individual modality for return to preinjury joint function at 10 days and 1 month following grade I and II sprains.
  - Grade III sprains should have short-term immobilization (10 days) with below-the-knee cast, followed by a semirigid brace (air cast). If a patient refuses casting, a 10-day period of strict non–weight-bearing with air cast splint and elastic bandage is a comparable alternative if non–weight-bearing is maintained.
- Rest: initially, activity as tolerated. Early mobilization and physical therapy speed recovery/reduce pain:
  - Weight-bearing, as tolerated
  - Consider crutches if unable to bear weight.
  - Initiate exercises as early as tolerated. Limit to pain-free range of motion.
  - Start mobilization by tracing the alphabet with the foot or toes.
  - Resistance exercises with an elastic band
- Ice: Ice for first 3 to 7 days reduces pain and decreases recovery time.
- Elevation: Elevate ankle to decrease swelling.

MEDICATION

- NSAIDs: preferably oral; topical forms (e.g., diclofenac 1% gel) may be used to minimize GI side effects. PRN NSAID dosing has similar outcomes to scheduled dosing with improved safety profile.
  - Example: naproxen 500 mg BID PRN
- Acetaminophen 650 mg q4–6h (max outpatient therapy dose: 3,250 mg/day)
- Opioids (<5 days) if severe pain

ISSUES FOR REFERRAL

- Malleolar/talar dome fracture
- Syndesmotic sprain
- Dislocation/subluxation
- Tendon rupture
- Ongoing instability
- Uncertain diagnosis

ADDITIONAL THERAPIES

Physical therapy:
- After the acute phase of the injury, patients with grade II or III sprain should start physical therapy as soon as possible to increase range of motion, strength, flexibility, and improve proprioceptive balance (wobble board/ankle disk).
- Functional rehabilitation prevents chronic instability and speeds healing.
• Athletes should undergo sport-specific rehabilitation before returning to play.

**SURGERY/OTHER PROCEDURES**
• Surgery is typically reserved for treatment of complicated recurrent sprains and certain syndesmotic sprains.
• Patients with chronic ankle instability who fail functional rehabilitation or with poor tissue quality may need anatomic repair/reconstructive surgery.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
• After an ankle sprain, consider ankle-stabilizing orthoses (air stirrup braces, lace-up supports, athletic taping, etc.) for athletes participating in high-risk sports to prevent future ankle sprains.
• Moderate and severe sprains require ankle orthoses for ≥6 months during sports participation.
• Gradual return to play for athletes with a grade I lateral ankle sprain can generally be accomplished in 1 to 2 weeks; grade II sprain return to play time is 2 to 3 weeks; grade III sprain is approximately 4 weeks.
• Syndesmotic sprains take longer (~8 to 9 weeks) to heal than lateral ankle sprains.

**Patient Monitoring**
If athletes continue to have symptoms when they return to play or if a patient has pain for 6 to 8 weeks after injury, repeat examination and imaging.

**PATIENT EDUCATION**
• Crutch training
• Provide training on proper use of elastic bandages, brace, and/or orthoses.
• Demonstrate mobilization exercises (alphabet trace, towel grab).

**PROGNOSIS**
• Earlier physical therapy and mobilization with bracing allows for faster return to daily living and/or sports.
• Higher grade sprains, older patient age, and initial non–weight-bearing status have poorer prognosis and longer recovery.
• Ligamentous strength does not return for months after the injury.

**COMPLICATIONS**
• Joint instability
• Intermittent swelling/pain if not properly treated
• 5–33% continue to have pain 1 year postinjury.
• Accumulation of cartilage damage, leading to degenerative changes

**REFERENCES**

ADDITIONAL READING

CODES

ICD10

- S96.919A Strain of unsp msl/tnd at ank/ft level, unsp foot, init
- S93.499A Sprain of other ligament of unspecified ankle, init enctr
- S93.419A Sprain of calcaneofibular ligament of unsp ankle, init

CLINICAL PEARLS

- Children are at an increased risk of physeal injuries because ligaments are stronger than physis.
- Conditioning, including proprioceptive training, before participating in sports and throughout the season helps to prevent ankle sprains.
- Functional rehabilitation, rather than total immobilization, is recommended for quicker return to sport and work.
- Patients who do not adequately rehabilitate an ankle sprain are at increased risk for recurrence and chronic ankle instability.
- If patient’s condition is not improving in 6 to 8 weeks, consider advanced imaging with CT, MRI, or US.
SPRAINS AND STRAINS
J. Herbert Stevenson, MD • James McKee, DO, MS

BASICS

DESCRIPTION
- Sprains are complete or partial ligamentous injuries either within the body of the ligament or at the site of attachment to bone.
  - Classified as grade 1, 2, or 3 (AMA Ligament Injury Classification)
    - Grade 1: stretch injury without ligamentous laxity
    - Grade 2: partial tear with increased ligamentous laxity but firm end point on exam
    - Grade 3: complete tear with increased ligamentous laxity and no firm end point on exam
  - Usually secondary to trauma (e.g., falls, twisting injuries, motor vehicle accidents)
  - Physical exam is the key to accurate diagnosis.
- Strains are partial or complete disruptions of the muscle, muscle–tendon junction, or tendon.
  - Classified as
    - First degree: minimal damage to muscle, tendon, or musculotendinous unit
    - Second degree: partial tear to the muscle, tendon, or musculotendinous unit
    - Third degree: complete disruption of the muscle, tendon, or musculotendinous unit
  - Often associated with overuse injuries

Geriatric Considerations
More likely to see associated bony injuries due to decreased joint flexibility and increased prevalence of osteoporosis and osteopenia

Pediatric Considerations
- Sprains and strains account for 24% of pediatric injuries.
- 3 million pediatric sports injuries occur annually.
- Consider physeal/apophyseal injuries in the skeletally immature patient.

EPIDEMIOLOGY

Incidence
~80% of all U.S. athletes experience a sprain or strain at some point.

Prevalence
- Ankle sprains are among the most common injuries in primary care, accounting for ~30% of sports medicine clinic visits. Most ankle sprains are due to inversion injuries (lateral sprains) involving the anterior talofibular ligament; account for 650,000 annual ER visits in the United States
- Predominant age
  - Sprains: any age in physically active patient
  - Strains: usually 15 to 40 years of age
- Predominant sex: male > female for most; female > male for sprain of anterior cruciate ligament (ACL)

ETIOLOGY AND PATHOPHYSIOLOGY
Trauma, falls, motor vehicle accidents
Excessive exercise; poor conditioning
Improper footwear
Inadequate warm-up and stretching before activity
Prior sprain or strain

RISK FACTORS
- Prior history of sprain or strain is greatest risk factor for future sprain/strain.
- Change in or improper footwear, protective gear, or environment (e.g., surface)
- Sudden increase in training schedule or volume
- Tobacco use, medication adverse effects

GENERAL PREVENTION
- Appropriate warm-up and cooldown exercises
- Use proper equipment and footwear.
- Balance training programs improve proprioception and reduce the risk of ankle sprains.
- Semirigid orthoses may prevent ankle sprains during high-risk sports, especially in athletes with history of sprain.
- Proprioception and strength training decrease injury risk; stretching does not.

COMMONLY ASSOCIATED CONDITIONS
- Effusions, ecchymosis, hemarthrosis
- Stress, avulsion, and/or other fractures
- Syndesmotic injuries
- Contusions
- Dislocations/subluxations

DIAGNOSIS

HISTORY
- Obtain thorough description of mechanism of injury including activity, trauma, baseline conditioning, and prior musculoskeletal injuries.
- May describe feeling or hearing pop or snap

PHYSICAL EXAM
- Inspect for swelling, asymmetry, ecchymosis, and gait disturbance.
- Evaluate for neurovascular compromise.
- Palpate for tenderness.
- Evaluate for decreased range of motion (ROM) of joint and joint instability/laxity.
- Evaluate for strength.
- Sprains
  - Grade 1: tenderness without laxity; minimal pain, swelling; little ecchymosis; can bear weight
  - Grade 2: tenderness with increased laxity on exam but firm end point; more pain, swelling; often ecchymosis; some difficulty bearing weight
  - Grade 3: tenderness with increased laxity on exam and no firm end point; severe pain, swelling; obvious ecchymosis; difficulty bearing weight
DIFFERENTIAL DIAGNOSIS
- Tendinitis
- Bursitis
- Contusion
- Hematoma
- Fracture
- Osteochondral lesion
- Rheumatologic process

DIAGNOSTIC TESTS & INTERPRETATION
- **Ankle**
  - Anterior drawer test assesses integrity of anterior talofibular ligament.
  - Talar tilt test assesses integrity of calcaneofibular ligament.
  - Squeeze test assesses for syndesmotic injury.
  - Palpate lateral and medial malleoli.
- **Knee**
  - Lachman and anterior drawer tests assess integrity of ACL. Posterior drawer and sag tests assess integrity of posterior cruciate ligament.
  - Valgus/varus stress tests assess integrity of medial and lateral collateral ligaments, respectively.
- **Shoulder**
  - Load and shift test; sulcus sign; and the apprehension, relocation, surprise test assess for instability of the glenohumeral joint.
- **Radiographs** help rule out bony injury; stress views may be necessary. Obtain bilateral radiographs in children to rule out growth plate injuries.
- **Use Ottawa Foot and Ankle Rules (age 18 to 55 years)** to determine if radiographs are necessary.
  - Ottawa Ankle Rules: x-ray required if pain in the malleolar zone and
    - Bone tenderness in posterior aspect distal 6 cm of tibia or fibula or
    - Unable to bear weight immediately or in emergency department
  - Ottawa Foot Rules: x-ray required if midfoot zone pain is present and
    - Bone tenderness at base of 5th metatarsal or
    - Bone tenderness at navicular or
    - Inability to bear weight immediately or in emergency department

**Follow-Up Tests & Special Considerations**
- **CT scan** if occult fracture is suspected
- **Magnetic resonance imaging (MRI)** is the gold standard for imaging soft tissue structures, including muscle, ligaments, and intra-articular structures. If tibiofibular syndesmotic disruption is suspected, MRI is highly accurate for diagnosis.
- **Ultrasound evaluation** of a variety of muscles, tendons, and ligaments by a skilled operator allows for dynamic evaluation of potential sprain/strain that can add to traditional diagnostic imaging.

**Diagnostic Procedures/Other**
Surgery may be required for some partial and complete sprains depending on location, mechanism, and chronicity.
TREATMENT

GENERAL MEASURES

- Acute: protection, relative rest (activity modification), ice, compression, elevation, medications, modalities (PRICEMM) therapy
- Ankle sprains: Compression stockings didn’t affect pain, swelling, or time to pain-free walking but did show decreased time to return to sport (1)[B].
- Grade 1 and 2 ankle sprain: functional treatment with brace, orthosis, taping, elastic bandage wrap
  - Ankle braces (lace-up, stirrup-type, air cast) are a more effective functional treatment than elastic bandages or taping (2)[A].
- Grade 3 ankle sprain: Short period of immobilization may be needed.
- Refer for early physical therapy.
- For high-level athletes with more extensive damage (e.g., biceps or pectoralis disruption), consider surgical referral.

MEDICATION

First Line

- Acetaminophen: not to exceed 3 g/day
- NSAIDs
  - Ibuprofen: 200 to 800 mg TID
  - Naproxen: 250 to 500 mg BID
  - Diclofenac: 50 to 75 mg BID
- Opioids can be considered acutely for severe pain, but discretion is advised.
- Acetaminophen and NSAIDs have similar efficacy in reducing pain after soft tissue injuries with less GI side effects; NSAIDs are better than narcotics.
- Topical diclofenac, ibuprofen, and ketoprofen are effective for pain related to strains and sprains, especially in gel form or patch (3)[A].
- Platelet-rich plasma injections may aid recovery in treatment of muscle strains, but more studies are needed.

ISSUES FOR REFERRAL

- ACL sprain in athletes/physically active
- Salter-Harris physeal fractures
- Joint instability especially if chronic
- Tendon disruption (i.e., Achilles, biceps, ACL)
- Lack of improvement with conservative measures

ADDITIONAL THERAPIES

- Physical therapy is a useful adjunct after a sprain, particularly if early mobilization is crucial.
  - Proprioception retraining
  - Core strengthening
  - Eccentric exercises
  - Thera-Band exercises
- After hamstring strain, frequent daily stretching and progressive agility and trunk stabilization exercises may speed recovery and reduce risk of reinjury (4)[A]. Rehab protocols emphasizing
eccentric/lengthening exercises are more effective than conventional exercises (5)[B].

SURGERY/OTHER PROCEDURES
- Casting and surgery are reserved for select partial and complete sprains. Need for surgery depends on the neurovascular supply to the injured area as well as the ability to attain full ROM and stability of the affected joint. The need for surgery also depends on activity level and patient preference.
- For primary management of acute lateral ankle sprains, there is no difference between surgical versus conservative therapy. Risks are increased with surgical intervention.
- Chronic ankle instability affects 10–20% of people who sustain an acute sprain. If conservative management fails and laxity is present, surgery is considered (6)[A].
- Percutaneous needle tenotomy versus surgical tenotomy are available as options for chronic tendinosis (chronic, recurrent strains).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
If the affected joint has full strength and ROM, the patient can advance activity as tolerated using pain as a guide for return to activity.

Patient Monitoring
After initial treatment, consider early rehabilitation. Limit swelling and work on increasing ROM.

DIET
Weight loss if overweight

PATIENT EDUCATION
- Injury prevention through proprioceptive training and physical therapy
- ROM and strengthening exercises to restore functional capacity

PROGNOSIS
Favorable with appropriate treatment and rest. Duration of recovery depends on the severity and location of injury.

COMPLICATIONS
- Chronic joint instability
- Arthritis
- Muscle contracture
- Chronic tendinopathy

REFERENCES

Tendinopathy

CODES

ICD10

- S93.409A Sprain of unsp ligament of unspecified ankle, init encntr
- S96.919A Strain of unsp msl/tnd at ank/ft level, unsp foot, init
- S43.50XA Sprain of unspecified acromioclavicular joint, initial encounter

CLINICAL PEARLS

For acute injury, remember PRICEMM:
- Protection of the joint
- Relative rest (activity modification)
- Apply ice.
- Apply compression.
- Elevate joint.
- Medications/ice for pain
- Other modalities as needed
- Wean out of brace as tolerated to limit atrophy of stabilizing muscles.
SQUAMOUS CELL CARCINOMA, CUTANEOUS
Sara Usman, MBBS ▪ Sidra Saeed, MD ▪ Ghulam Murtaza, MD

Basics

Description
Cutaneous squamous cell cancer is a type of cancer that is very common. It is associated with some hereditary disorders like xeroderma pigmentosum, oculocutaneous albinism, epidermodysplasia verruciformis.

Epidemiology

Incidence
- Occurs in older age (around 60 years) (1)
- More common in men (1)
- Incidence increases the closer the person gets to equator or higher altitude (1).

Prevalence
Average age it develops is 70 years.

Etiology and Pathophysiology

Genetics
Some of the hereditary disorders have the genes that are associated with cutaneous squamous cell cancer (2). They include:
- Xeroderma pigmentosum (2)
- Oculocutaneous albinism (2)
- Epidermodysplasia verruciformis (2)
- Genes commonly mutated includes:
  - TP53
  - CDKN2A
  - NOTCH1, Ras
  - TP53 is the most common gene involved in cutaneous squamous cell cancer.

Risk Factors
- UV radiation exposure (2,3)
- Increasing age (Average age of onset is mid-60s.)
- Immunosuppression (2)
- HIV/AIDS, non-Hodgkin lymphoma, chronic lymphocytic leukemia have increase rates of developing cutaneous squamous cell cancer (2).
- Gender (more common in men)
- Psoriasis patients treated with ultraviolet A (UVA)
- Glucocorticoid use (2)
- Postmenopausal hormonal use (2)
- High body mass
- Ionizing radiation exposure (3)
- Chemical exposure (pesticides, PAH) (2)
- Arsenic (2,3)
Organ transplantation (3)
- Alcohol use (2)
- Osteomyelitis (3)
- Exposure to UV light (UVA and UVB)
- Xeroderma pigmentosum (3)
- Ulcers (3)
- Chronically injured or diseased skin (3)
- Actinic keratosis (2, 3)
- Radiation-induced keratosis (3)
- Precursor lesions (3)
- Bowen disease (squamous cell carcinoma [SCC] in situ) (3)
- Erythroplasia of Queyrat (SCC in situ of penis) (3)
- Leukemia (3)
- Lymphoma (3)
- Immunosuppression (3)
- Organ transplantation (3)
- Immunosuppressive medications (3)
- HPV infection (6, 11, 16, 18) (3)

**GENERAL PREVENTION**
- Protect skin from sun exposure (2).
- Wear sunscreen, hats, and clothing under skin.
- Vitamin B₃ (nicotinamide) can repair DNA by preventing UVR-induced adenosine triphosphate depletion (2).
- Difluoromethylornithine (synthetic analog of ornithine) (2)

**COMMONLY ASSOCIATED CONDITIONS**
- Actinic keratosis is the precursor of cutaneous squamous cell cancer (1).
- Diseases that evolve into squamous cell cancer include:
  - Bowen disease (1)
  - Erythroplasia of Queyrat (1)

**DIAGNOSIS**

**PHYSICAL EXAM**
- Lesions occur mainly on chronically exposed areas:
  - Face (especially lips, ear, nose, cheek, and eyelid) (1)
- Lesions occur chiefly on chronically sun-exposed areas.
  - Face and backs of the forearms and hands
  - Bald areas of the scalp and top of ears in men
  - The sun-exposed “V” of the neck as well as the posterior neck below the occipital hairline
  - In elderly females, lesions tend to occur on the legs and other sun-exposed locations.
  - In African Americans, equal frequency in sun-exposed and unexposed areas
- Clinical appearance
  - Generally slow-growing, firm, hyperkeratotic papules, nodules, or plaques
  - Most SCCs are asymptomatic, although bleeding, pain, and tenderness may be noted.
Lesions may have a smooth, verrucous, or papillomatous surface.
- Varying degrees of ulceration, erosion, crust, or scale
- Color is often red to brown, tan, or pearly (indistinguishable from basal cell carcinoma).

Clinical variants of SCC
- Bowen disease (SCC in situ): solitary lesion that resembles a scaly psoriatic plaque
- Invasive SCC: often a raised, firm papule, nodule, or plaque. Lesions may be smooth, verrucous, or papillomatous, with varying degrees of ulceration, erosion, crust, or scale.
- Cutaneous horn: SCC with an overlying cutaneous horn. A cutaneous horn represents a thick, hard, fingernail-like keratinization produced by the SCC. Bowen disease may also produce a cutaneous horn on its surface.
- Erythroplasia of Queyrat refers to Bowen disease of the glans penis, which manifests as one or more velvety red plaques.
- Subungual SCC appears as hyperkeratotic lesions under the nail plate or on surrounding periungual skin, often mimicking warts.
- Marjolin ulcer: an SCC evolving from a new area of ulceration or elevation at site of a scar or ulcer
- HPV-associated SCC: virally induced; an SCC most commonly seen as a new or enlarging warty growth on penis, vulva, perianal area, or periungual region
- Verrucous carcinoma: subtype of SCC that is extremely well differentiated, can be locally destructive, but rarely metastasizes. Lesions are “cauliflower-like” verrucous nodules or plaques.
- Basaloid SCC: less common than typical SCC; seen more often in men aged 40 to 70 years

DIFFERENTIAL DIAGNOSIS
- Actinic keratosis
- Keratoacanthoma

DIAGNOSTIC TESTS & INTERPRETATION

For high-risk cutaneous squamous cell cancer: These are the follow-up recommendations (4):
- Full skin exam and lymph node exam required every 2 to 6 months (4)
- Every 6 to 12 months for next 3 years
- Annually after 5 years (4)

For high-risk cutaneous squamous cell cancer with regional disease: These are the follow-up recommendations (4):
- Full skin exam and lymph node exam every 1 to 3 months (4)
- Every 2 to 4 months for the next year (4)
- Every 4 to 6 months until the 5th year (4)
- Every 6 to 12 months for patient’s lifetime (4)

TREATMENT

MEDICATION

First Line
- First-line treatment for cutaneous SCC is complete surgical excision with histopathologic control of excision margins.
Surgical excision provides these benefits (4):
- Shorter healing time
- Cure rate as high as 95%

Mohs micrographic surgery (MMS) is the treatment for high-risk tumors instead of surgical excision (4).
- MMS is gold standard for surgical removal of high-risk SCCs (4).
- SCCs with low risk of metastasis can be eliminated by excision, electrodesiccation and curettage, or cryosurgery.
- For high-risk cancer, surgical resection and MMS provide decreased recurrence and metastasis.
- Cryotherapy is used to treat small squamous cell cancers.
- Cryotherapy can be used as treatment for patients who have bleeding disorders or contraindications to surgery.
- MMS offers the highest cure for patients who have recurrent or high-risk primary squamous cell cancer.

Second Line
Advances in the management of cutaneous SCC
- Monoclonal antibodies (cetuximab, panitumumab) (4)
- Tyrosine kinase inhibitors (erlotinib) (4)
- Chemotherapy—used in locally advanced or metastatic skin squamous cell cancer (4)
- Chemotherapeutic drugs used are (4):
  - Methotrexate
  - Bleomycin
  - Doxorubicin
  - Cisplatin
- Oral retinoids decrease the incidence of actinic keratosis and cutaneous squamous cell cancer (4).

SURGERY/OTHER PROCEDURES
- For high-risk cutaneous squamous cell cancer patients, who have tumors in locations that are inoperable and are poor candidates for surgery, they have option for radiation therapy (4).
- Radiation therapy side effects include (4):
  - Malaise
  - Nausea
  - Radiation-induced erythema
  - Telangiectasia
  - Hypopigmentation
  - Epidermal atrophy
  - Soft tissue necrosis
  - Radiation-induced malignancy

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Examine sentinel lymph nodes for early detection of metastasis. This can decrease disease-related morbidity and mortality (4).
ONGOING CARE

PROGNOSIS

- Patients with high-risk cutaneous squamous cell cancer have increased risk of recurrence, lymph node, or distant metastases (4).
- From the lesions at risk, 7–80% will locally recur or metastasize within the first 2 years and 95% within the first 5 years of initial diagnosis (4).
- 30–50% of patients with high-risk cutaneous squamous cell cancer will develop second skin cancer within 5 years (4).
- Cutaneous squamous cell cancer has increased risk of metastasis if these characteristics below are present (4):
  - Tumor recurrence
  - Diameter ≥2 cm
  - Thickness >2 mm
  - Poorly differentiated histology
  - Invasion of subcutaneous tissue or structures such as perineural, vascular, or lymphatic
  - If tumor is located on
    o Eye
    o Vermillion lip
    o “Mask areas” of face
    o Hands
    o Feet
    o Genitalia
- MMS provides cure rates of 97% for primary cutaneous squamous cell cancer and 94% for recurrent cutaneous squamous cell cancer.
- MMS is very beneficial for treating specifically high-risk cutaneous squamous cell cancers and preventing local recurrence (4).
- Staging is important for treating high-risk cutaneous SCC (4).
- High risk factors include (4):
  - Diameter ≥0.1 mm
  - Poorly differentiated histology
  - Tumor invasion beyond fat
  - Perineural invasion ≥0.1 mm
- Excellent prognosis
- After recurrence, prognosis is very poor. There is risk of distant metastasis and metastasis to regional lymph nodes.
- After resection of the cancer, recurrent cancers have twice the risk of recurrence.
- Patients with metastatic disease, long-term prognosis is poor.
  - For patients having distant metastasis, 10-year survival rates are <10%.
  - For patients having regional lymph node involvement, 10-year survival rates are <20%.
- Distant metastasis occurs in 15% of cases and involves these sites:
  - Brain
  - Lungs
  - Liver
  - Skin
  - Bone
COMPLICATIONS

- Local recurrence
- Metastasis

REFERENCES

CODES

ICD10

- C44.92 Squamous cell carcinoma of skin, unspecified
- C44.320 Squamous cell carcinoma of skin of unspecified parts of face
- C44.42 Squamous cell carcinoma of skin of scalp and neck

CLINICAL PEARLS

- Cutaneous SCC associated with UV light exposure and immunosuppression
- Head and neck are the most common regions for invasive cutaneous SCC.
- MMS provides cure rates of 97% for primary cutaneous SCC.
STRESS FRACTURE
David A. Ross, MD, CAQSM

BASICS

DESCRIPTION

- Stress fractures are overuse injuries caused by cumulative microdamage from repetitive bone loading.
- Stress fractures occur in different situations:
  - Fatigue fracture: abnormal repetitive stress applied to normal bone (e.g., young college athletes or new military recruits with increased physical activity demands and inadequate conditioning). Common sites include tibia, fibula, metatarsals, femoral neck, and navicular.
  - Insufficiency fracture: normal stress applied to structurally abnormal bone (e.g., femoral neck fracture in osteopenic bone, metabolic bone disease). Common sites include spine, sacrum, femoral neck, and medial femoral condyle.
  - Combination fracture: abnormal stress applied to abnormal bone (e.g., female long-distance runners with premature osteoporosis from female athletic triad)
- Weight-bearing bones of the lower extremity are most commonly affected at the following sites:
  - Tibia/fibula
  - Metatarsal bones
  - Navicular
  - Femoral neck
  - Pars interarticularis
- Less commonly affected sites:
  - Pelvis
  - Calcaneus
  - Ribs
  - Ulna
- High-risk stress fractures occur in zones of tension or areas with poor blood supply and are more likely to result in fracture displacement and/or nonunion. High-risk sites include the following:
  - Tension side of femoral neck
  - Anterior tibial diaphysis
  - Sesamoids
  - Pars interarticularis of lumbar spine (L4, L5)
  - 5th metatarsal at metaphyseal–diaphyseal junction
  - Proximal 2nd metatarsal
  - Medial malleolus
  - Tarsal navicular
  - Patella
  - Talar neck
- Synonym(s): march fracture; fatigue fracture

EPIDEMIOLOGY
Incidence
- Greatest incidence in 15- to 27-year-olds
- Females have higher incidence as compared to males (attributed to female athlete triad) (1).
- Accounts for up to 20% of visits to sports medicine and orthopedic clinics
- Across all sports, the most commonly injured body sites are the lower leg, foot, and lower back/lumbar spine/pelvis.

Prevalence
- Occurs in <1% of general population
- Affects up to 6.9% of male and 21.0% of female military members (2)
- Affects 1–3% of college athletes
- Affects 9–21% of track and field athletes annually

ETIOLOGY AND PATHOPHYSIOLOGY
- Bone is dynamic and constantly remodeling in response to applied physiologic stress.
- Repetitive loading or overuse causes microfractures that fail to heal due to imbalance between bone resorption and bone formation.
- If microdamage accumulates in excess of reparation, bony fatigue leads to stress fracture.

RISK FACTORS
- Intrinsic (3)[A]
  - Females are at 2.3 times higher risk than males.
  - Female athlete triad (low energy availability with or without disordered eating, menstrual dysfunction, and low bone mineral density)
  - Females with disrupted menstrual cycles are 2 to 4 times more likely to sustain stress injury (1)[C].
  - History of previous stress fracture increases risk of future stress fracture by 5 times.
  - History of osteoporosis, osteomalacia, rheumatoid arthritis, prolonged corticosteroid therapy
  - Body composition: increased risk of stress fractures with body mass index (BMI) <19
  - Skeletal malalignment: pes cavus/planus, leg length discrepancies, excessive forefoot varus, tarsal coalitions, prominent posterior calcaneal process, tight heel cords
  - Biomechanical factors such as increased vertical loading rate (e.g., heel-to-toe running instead of forefoot striking)
  - Extremes of body size and composition
  - Previous inactivity or low aerobic fitness
- Extrinsic (3)[A]
  - Type of exercise: both male and female athletes who participate in running, track and field, cross country, and gymnastics are at highest risk.
  - Training regimen: Running >32 km/week increases risk by 2 times in all athletes and by 3 times in female athletes.
  - Nutritional/dietary habits: inadequate caloric intake or history of a diagnosed eating disorder
  - Rapid increase in mileage, running pace, or training volume
  - Inappropriate footwear
  - Hard training surface
  - Inadequate recovery or rest and training with fatigued muscle
– There is no evidence that use of oral contraceptives is related to stress fracture risk.

**GENERAL PREVENTION**
- Avoid abrupt increases in physical activity (no more than 10% increase in load per week).
- Reduce intensity and duration of activity if new-onset pain.
- Proper footwear (athletes should have a gait analysis prior to training)
- Increasing dynamic physical activity (jumping, plyometric training) increases bone density and resistance to mechanical stress.
- Decrease vertical loading rate either by switching to forefoot strike running or (if continuing with heel-to-toe strike) by using a heel pad insert.
- Shock-absorbing foot inserts may help.
- Increased calcium and vitamin D intake may reduce stress fractures in female runners and military recruits.
- Vitamin D supplementation (800 IU/day) in combination with calcium (2,000 mg/day) is effective in reducing fracture risk (2)[C].

**COMMONLY ASSOCIATED CONDITIONS**
- Osteoporosis/osteopenia
- Female athlete triad
- Metabolic bone disorders

**DIAGNOSIS**

**HISTORY**
- Insidious onset of vague bony pain over period of weeks. Pain is typically worse with physical activity.
- Rest initially relieves pain.
- If untreated, pain progresses and may occur earlier during training sessions or even at rest. Pain also becomes more localized.
- History of recent change in training intensity, alteration in training terrain, and/or footwear
- Assess dietary practices: energy availability, disordered eating, weight fluctuations, and calcium and vitamin D intake
- In female athletes, assess menstrual history: menarche, oligomenorrhea, or amenorrhea.

**PHYSICAL EXAM**
- Height, weight, BMI, and any stigmata of disordered eating (cold extremities, hypercarotenemia, lanugo hair, calluses on back of fingers, poor oral hygiene, parotid gland hypertrophy, or orthostatic hypotension)
- Antalgic gait
- Point or percussion tenderness over injury site: A vibrating tuning fork over the fracture site may intensify pain.
- Swelling may be present.
- Specific tests:
  - Hop test for tibial stress fracture: With a stress fracture, the patient cannot hop on one leg 10 times; if able to perform test, consider shin splints (medial tibial stress syndrome).
  - Fulcrum test for femoral stress fracture: With patient seated, provoke pain by applying downward force on the distal femur while other hand uses the midthigh as fulcrum on
femoral shaft (if clinical suspicion is high, defer or use only with extreme caution to avoid completing a femoral neck stress fracture).

– Single-leg hyperextension (Stork) test for pars interarticularis fracture of lumbar spine:
  Stand on one leg and extend lumbar spine; positive if painful on symptomatic side

● Anatomic malalignment may be present (leg length discrepancy, scoliosis, pes planus/cavus).

DIFFERENTIAL DIAGNOSIS

● Shin splints (medial tibial stress syndrome—pain resolves with rest; stress fracture pain does not)
● Infection (osteomyelitis)
● Soft tissue injury (sprain, tendonitis, and periostitis)
● Exertional compartment syndrome
● Bony fracture
● Neoplasm (osteoid osteoma)
● Nerve entrapment syndromes
● Intermittent claudication

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

● Laboratory tests are not required unless clinically indicated for suspected disease (e.g., female athlete triad, hyperparathyroidism, vitamin D deficiency).
● If nutritional or metabolic causes are suspected, consider testing for 25-hydroxyvitamin D3, calcium, TSH, FSH, LH, CBC, and BMP (2)[C].
● Plain films (x-ray):
  – First line in suspected stress fracture
  – Findings typically seen 2 to 8 weeks after pain onset
  – Sensitivity during early stages (1 to 2 weeks) may be as low as 10%.
  – May see periosteal callus, “gray cortex sign” (region of decreased cortical intensity), osteopenia, endosteal reaction, or ill-defined cortical margin
  – Severe cases may show discrete fracture.

Follow-Up Tests & Special Considerations

● MRI:
  – Gold standard for imaging stress fractures
  – Highly sensitive (sensitivity 100%, specificity 85%); more complete evaluation of exact anatomic location and extent of injury (2)[C]
● Bone scan:
  – Sensitive but has potential for false positives
  – Useful for suspected rib or spine stress fractures
  – Should not be used to assess healing, increased uptake on all three phases of bone remodeling (2)[C]
● CT scan:
  – Less sensitive than MRI or bone scan for early stress fractures but has an important role in evaluating longitudinal fracture lines and occult fractures of foot, tibia, carpal scaphoid, and pars interarticularis
  – Can distinguish conditions (osteoid osteoma, malignancy, and osteomyelitis) that mimic stress fracture on bone scan
Bony detail provided by CT scan allows differentiation of complete versus incomplete fracture, especially if MRI is equivocal.

- Ultrasound: not routinely used but beneficial for superficial stress fracture; may help to distinguish metatarsal stress fracture from other causes of metatarsalgia (e.g., Morton neuroma) (2)[C]

- Classification by radiographic findings (CT, MRI, bone scan, or x-ray) (4)[C]
  - Grade I: asymptomatic stress reaction; no pain, periosteal edema only, no fracture line
  - Grade II: symptomatic stress reaction; pain on exam, bone marrow edema, no fracture line seen on imaging
  - Grade III: nondisplaced fracture; pain on exam, nondisplaced fracture line seen on imaging
  - Grade IV: displaced fracture; pain on exam, displaced fracture >2 mm seen on imaging
  - Grade V: nonunion; pain on exam, nonunion characteristics on imaging, long-standing symptoms

**TREATMENT**

- Grade I to grade II and low-risk stress fractures are generally treated nonoperatively, including non–weight-bearing and immobilization (5)[C].

- Grade III to grade V and high-risk stress fractures are treated either operatively or nonoperatively based on the imaging characteristics and fracture site (5)[C].

- Protection, rest, ice, compression, and elevation (PRICE) for acute pain and edema

- Decrease activity to the level of pain-free functioning.

- Consider temporarily immobilizing patients who have pain at rest or with gentle range of motion.

- If patients have pain with ambulation, use crutches with periodic walking trial to monitor readiness for nonaided (pain free) ambulation.

- Pneumatic leg brace is effective in decreasing the return-to-play time for tibial shaft stress fracture.

- For low-risk stress fracture, slowly increase impact loading once ambulation and daily activities are pain free. Progression of activity depends on the individual and should be modified according to symptoms (5,6)[C].

- High-risk fractures typically require immediate immobilization and a period of non–weight-bearing. Many patients require early surgical intervention to avoid nonunion and facilitate earlier return to sport (5)[C].

- A key difference between a low-grade stress fracture at a high-risk location versus a low-risk location is that with the low-risk site, the athlete could be allowed to continue to train, whereas the high-risk site needs to heal prior to full return to activity.

- Criteria for allowing an athlete to return should include complete resolution of symptoms with activities of daily living; radiographic evidence of healing; no tenderness to palpation at the injury site; and optimization of the athlete’s nutritional, biomechanical, hormonal, and psychological status.

**MEDICATION**

**First Line**

- Calcium and vitamin D (800–4,000 IU/day) supplementation should be initiated when dietary intake is inadequate or deficiencies are found.
Acetaminophen is useful for pain.
NSAIDs are beneficial for pain and inflammation but may adversely affect fracture healing and should, therefore, be used only sparingly.

ISSUES FOR REFERRAL
Orthopedic consultation for high-risk fractures, failure to improve with standard treatment, evidence of nonunion within 3 to 4 weeks, or inability to tolerate rehabilitation

ADDITIONAL THERAPIES
- Electrical stimulation may be an adjunct for delayed union and nonunion.
- Extracorporeal shock wave therapy (ESWT) and pulsed US may have potential benefit but require additional study.
- Physical therapy:
  - Correct training errors and inappropriate mechanics predisposing to stress fracture.
  - Strengthen surrounding musculature.
  - Encourage cross-training to maintain fitness.
  - Correct anatomic variations.
  - Antigravity treadmills

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Once the patient is pain free, low-impact training can start and be advanced gently as tolerated.
- Once running has resumed, increase mileage slowly no more than 10% per week.

Patient Monitoring
- Imaging every 4 to 6 weeks to assess healing.
- An MRI is the preferred imaging technique for follow-up of early stage stress fractures.
- Radiographs are less expensive and can be used for follow-up of higher grade stress fractures.

DIET
- Ensure that the patient has adequate caloric intake for their athletic training requirements.
- Patient should have adequate dietary intake of calcium and vitamin D.

PATIENT EDUCATION
- Gradually increase activity as long as pain free.
- Rest and reevaluate if there is a recurrence of pain.
- Correct mechanical and training errors with gait retraining.
- Evaluate nutrition and ensure adequate caloric, calcium, and vitamin D intake.

PROGNOSIS
- Young patients have a good prognosis.
- Older patients or those with metabolic bone disease often develop insufficiency fractures in other bones.
- Time to return to full activity (5)
  - Grade I: 3+ weeks
  - Grade II: 5+ weeks
– Grade III: 11+ weeks
– Grade IV and V: 14+ weeks

COMPLICATIONS
- Completion of fracture
- Delayed union
- Nonunion
- May require surgery with internal fixation if progresses or with delayed healing/nonunion

REFERENCES

ADDITIONAL READING

SEE ALSO
Algorithm: Foot Pain

CODES
ICD10
- M84.38XA Stress fracture, other site, initial encounter for fracture
- M84.369A Stress fracture, unspec tibia and fibula, init for fx
- M84.376A Stress fracture, unspecified foot, init encntr for fracture

CLINICAL PEARLS
- The diagnosis of stress fractures requires a high index of suspicion. X-rays are often negative initially.
• Identify and treat female athletic triad to prevent stress fractures.
• To help prevent stress fractures, gradually increase training volume and avoid sudden increases in high-impact activity or running mileage.
• To help prevent stress fractures, ensure adequate nutrition intake including calcium and vitamin D.
• High-risk fractures require immediate immobilization and non-weight-bearing. Patients may also require early surgery.
**STROKE, ACUTE (CEREBROVASCULAR ACCIDENT [CVA])**
Jeanne M. Cawse-Lucas, MD • Daniel L. Cornish, MD

**BASICS**

**DESCRIPTION**
The sudden onset of a focal neurologic deficit(s) resulting from either infarction or hemorrhage within the brain
- Two broad categories: ischemic (thrombotic or embolic) (87%) and hemorrhagic (13%)
- Hemorrhage can be intracerebral or subarachnoid.
- System(s) affected: neurologic; vascular (1)
- Synonym(s): CVA; cerebral infarct
- Related terms: transient ischemic attack (TIA), a transient episode of neurologic dysfunction due to focal ischemia without permanent infarction on imaging (see topic “Transient Ischemic Attack [TIA]”)

**Pediatric Considerations**
- Incidence: 2 to 13/100,000
- Frequent risk factors: arteriopathies (53%), cardiac disorders (31%), and infection (24%) (2)

**EPIDEMIOLOGY**

**Incidence**
Annual incidence in the United States is ~795,000.

**Prevalence**
- Prevalence in the United States: 550/100,000
- Predominant age: Risk increases >45 years of age and is highest during the 7th and 8th decades.
- Predominant sex: male > female at younger age but higher incidence in women age ≥75 years

**ETIOLOGY AND PATHOPHYSIOLOGY**
- 87% of strokes are ischemic, three main subtypes: thrombosis, embolism, and systemic hypoperfusion. Large vessel atherothrombotic strokes often involve the origin of the internal carotid artery. Small vessel lacunar strokes are commonly due to lipohyalinotic occlusion. Embolic strokes are largely from a cardiac source (due to left atrial thrombus, atrial fibrillation, recent MI, valve disease, or mechanical valves) or ascending aortic atheromatous disease (>4 mm) (1).
- 13% of strokes are hemorrhagic; most commonly due to hypertension. Other causes include intracranial vascular malformations (cavernous angiomas, arteriovenous malformations), cerebral amyloid angiopathy (lobar hemorrhages in elderly), and anticoagulation (1).
- Fibromuscular dysplasia (rare), vasculitis, or drug use (cocaine, amphetamines) are other causes of stroke.

**Genetics**
Stroke is a polygenic multifactorial disease.
RISK FACTORS
- Uncontrollable: age, gender, race, family history/genetics, prior stroke or TIA
- Controllable/modifiable/treatable
  - Metabolic: diabetes, dyslipidemia
  - Lifestyle: smoking, cocaine, and amphetamine use
  - Cardiovascular: hypertension, atrial fibrillation, valvular heart disease, endocarditis, recent MI, severe carotid artery stenosis, hypercoagulable states, and patent foramen ovale (1)

GENERAL PREVENTION
Smoking cessation; regular exercise; weight control to maintain nonobese body mass index and prevent type 2 diabetes; moderate alcohol use; control blood pressure (BP); manage hyperlipidemia; use antiplatelet agent (e.g., aspirin) in high-risk persons; treat nonvalvular atrial fibrillation with dose-adjusted warfarin or dabigatran, apixaban, and rivaroxaban (3).

COMMONLY ASSOCIATED CONDITIONS
Coronary artery disease is the major cause of death during the first 5 years after a stroke.

DIAGNOSIS

HISTORY
- Determining time course is critical—assess onset of symptoms.
- Acute onset of focal arm/leg weakness, facial weakness, difficulty with speech or swallowing, vertigo, visual disturbances, diminished consciousness
- Assess risk factors.
- Vomiting and severe headache favor hemorrhagic stroke (1).

PHYSICAL EXAM
- Assess airway, breathing, and circulation (ABC).
- Vital signs—particularly pulse (character and rate) and blood pressure
- Cardiovascular exam: bruits, pulses (regularity); murmurs; gallops; peripheral stigmata
- Pulmonary exam: signs of fluid overload or bronchospasm
- Neurological exam:
  - Anterior (carotid) circulation: hemiparesis/hemiplegia, neglect, aphasia, visual field defects
  - Posterior (vertebrobasilar) circulation: diplopia, vertigo, gait and limb ataxia, facial paresis, Horner syndrome, dysphagia, dysarthria, alternating sensory loss
- The three most predictive findings for stroke on physical examination are: 1) facial paresis, 2) arm weakness or drift, 3) abnormal speech.

DIFFERENTIAL DIAGNOSIS
- Migraine (complicated)
- Postictal state (Todd paralysis)
- Systemic infection, including meningitis or encephalitis (infection also may uncover or enhance previous deficits)
- Toxic or metabolic disturbance (hypoglycemia, acute renal failure, liver failure, drug intoxication)
- Brain tumor, primary or metastases
- Head trauma, encephalopathy
Other types of intracranial hemorrhage (epidural, subdural, subarachnoid)
Trauma, septic emboli (1)

**DIAGNOSTIC TESTS & INTERPRETATION**
Used to narrow differential and identify etiology of stroke

**Initial Tests (lab, imaging)**
- Serum glucose (required to exclude hypo/hyperglycemia prior to IV alteplase) (3)[B]
- Electrocardiogram (ECG)
- Complete blood count; electrolyte panel
- Coagulation studies: prothrombin time, partial thromboplastin time, international normalized ratio (INR)
- Electrocardiogram
- Baseline troponin (3)[B]
- Emergent noncontrast head computed tomography (CT), within 20 minutes of arrival to the emergency department (3)[B]
- Subsequent multimodal CT (perfusion CT, computed tomography angiography, unenhanced CT) or magnetic resonance imaging (MRI) improves diagnosis of acute ischemic stroke (AIS).

**Follow-Up Tests & Special Considerations**
Consider liver function test, tox screen, blood alcohol, arterial blood gas, lumbar puncture if suspected subarachnoid hemorrhage (SAH); EEG if suspect seizures, blood type and cross
- Diffusion weighted (DW)-MRI is more sensitive than CT for acute ischemic stroke.
- MRI is better than CT for posterior fossa lesions.
- Prior to initiation of IV tissue plasminogen activator (tPA), a noncontrast head CT (rule out immunohistochemical [ICH]) and glucose are the only required tests unless contraindications exist. MRI to rule out cerebral microbleeds is not required (3)[B].
- Multimodal imaging studies should not delay IV tPA if indicated (3)[B].
- For patients who meet criteria for mechanical thrombectomy, multimodal CT and MRI to rule out large vessel occlusion is recommended (3)[A]. Selected patients may be treated up to 16 to 24 hours after onset of symptoms (3)[A].

**Diagnostic Procedures/Other**
Echocardiogram (transthoracic and/or transesophageal) if there is suspicion for cardioembolic source (3). In cryptogenic stroke patients, perform prolonged ECG monitoring with a 30-day event monitor.

**Test Interpretation**
Early CT findings of ischemia: hyperdense middle cerebral artery (MCA) sign (increased attenuation of proximal portion of the MCA; associated with MCA thrombosis), loss of gray-white matter differentiation, sulcal effacement, loss of insular ribbon

**TREATMENT**
- Monitor BP closely in the first 24 hours.
  - Withhold antihypertensives unless systolic BP >220 mm Hg or diastolic BP >120 mm Hg.
  - Goal is to lower BP ~15% in the first 24 hours if treatment is undertaken. If thrombolytic
therapy is planned, BP must be <185/110 mm Hg prior to administration of thrombolytics (3).

– In acute spontaneous intracranial hemorrhagic stroke, goal BP is 160/90 mm Hg or MUTYH-associated polyposis of 110 (see topic “Subarachnoid Hemorrhage” for details).
– If there is suspicion of elevated intracranial pressure (ICP), reduce BP to a target cerebral perfusion pressure of between 61 mm Hg and 80 mm Hg.
– Start/restart antihypertensive medications 24 hours after stroke onset for patients with BP >140/90 mm Hg who are neurologically stable (3)[B].

** ALERT **
Thrombolysis: Individualize discussion about the use of IV thrombolysis with eligible patients who have measurable neurologic deficits that do not clear spontaneously and present within 3 to 4.5 hours of symptom onset.

- Exclusion criteria for thrombolysis within 3 hours of onset include:
  - Any history of ICH or new symptoms suggestive of ICH (3)[B]
  - Head trauma or prior stroke within 3 months
  - MI within 3 months
  - GI malignancy or bleed within 21 days (3)[C]
  - Major surgery within 14 days
  - Arterial puncture at noncompressible site within 7 days
  - Elevated BP (systolic >185 mm Hg and diastolic >110 mm Hg)
  - Active bleeding or evidence of acute trauma on examination
  - Taking anticoagulant and INR ≥1.7
  - If low-molecular-weight heparin received during previous 24 hours (3)[B]; platelet count <100,000 mm$^3$ (3)[C]
  - Blood glucose concentration <50 mg/dL
  - Seizure with postictal residual neurologic impairment
  - Multilobar infarction on CT (hypodensity >1/3 cerebral hemisphere)
  - Patient or family members not able to provide input and understand potential harms and benefits of treatment

- Extended American Heart Association/American Society of Anesthesiologists exclusion criteria for thrombolysis within 4.5 hours include:
  - Age >80 years
  - All patients taking oral anticoagulants regardless of INR
  - National Institutes of Health (NIH) Stroke Scale >25
  - History of stroke and diabetes

** MEDICATION **

** First Line **

- Thrombolysis, IV administration of rtPA: Infuse 0.9 mg/kg, maximum dose 90 mg over 60 minutes with 10% of dose given as bolus over 1 minute.
  - Centers should attempt door-to-needle times of <60 minutes (3)[A].
  - Admit to ICU or stroke unit, with neurologic exams every 15 minutes during infusion, every 60 minutes for next 6 hours, and then hourly until 24 hours after treatment.
  - Discontinue infusion and obtain emergent CT scan if severe headache, angioedema, acute hypertension, or nausea and vomiting develop.
Measure BP every 15 minutes for first 2 hours, every 30 minutes for next 6 hours, and then every hour until 24 hours after treatment. Maintain BP <185/105 mm Hg; follow-up CT at 24 hours before starting anticoagulants or antiplatelet agents.

- **Antiplatelet:** aspirin 160 to 300 mg/day within 24 to 48 hours after AIS (3)[A]
- **BP management options include:**
  - Labetalol 10 to 20 mg IV over 1 to 2 minutes, which may be repeated once
  - Nicardipine infusion 5 mg/hr, titrate up by 2.5 mg/hr at 5- to 15-minute intervals to maximum of 15 mg/hr; reduce to 3 mg/hr when target BP is reached.

**Second Line**

Carotid endarterectomy (CEA) for carotid artery stenosis rarely is indicated emergently. CEA is indicated for >70% ipsilateral stenosis. CEA for TIA or incomplete stroke lesion may be indicated for 50–69% stenosis in carefully selected patients, depending on risk factors, and skill and experience of surgeons.

**ISSUES FOR REFERRAL**

Follow-up with neurologist 1 week after discharge, with subsequent follow-up based on individual circumstances

**ADDITIONAL THERAPIES**

- If no contraindications, a trial of fluoxetine to improve motor outcomes may be reasonable (4) [A].
- Deep vein thrombosis (DVT) prophylaxis for immobilized patients
- Corticosteroids are not recommended for cerebral brain edema.
- Statin use should be continued without interruption following acute stroke.
- Refer to physical therapy, occupational therapy, and speech therapy as necessary.

**SURGERY/OTHER PROCEDURES**

- Ventricular drain may be placed for patients with acute hydrocephalus secondary to stroke (most commonly cerebellar stroke).
- Decompressive surgery is recommended for major cerebellar infarction; consider for malignant MCA infarction, especially if <60 years of age.
- Consider mechanical embolectomy in carefully selected patients who have evidence of salvageable tissue on advanced imaging.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

Acupuncture within 30 days of stroke onset may improve neurologic functioning.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Observe closely within first 24 hours for neurologic decline, particularly due to cerebral edema.
- Elevate bed to at least 30 degrees if elevated ICP is suspected. Patients with ischemic stroke may benefit from a horizontal bed position during the acute phase.
- Monitor cardiac rhythm for at least 24 hours to identify arrhythmias.
- Airway support and ventilatory assistance may be necessary due to diminished consciousness or bulbar involvement; reserve supplemental oxygen for hypoxic patients (3). Consider elective intubation for patients with malignant edema.
- Correct hypovolemia with normal saline.
- Keep patients NPO until a formal swallow evaluation has been performed; to reduce risk of aspiration pneumonia, elevate head of bed to 30 degrees.
- Hypoglycemia can cause neurologic dysfunction; correct during initial evaluation.
- Hyperglycemia within first 24 hours of stroke is associated with poor outcomes: insulin recommended to maintain glucose levels 140 to 180 mg/dL (3).
- In patients with ICH secondary to anticoagulant use, correct an elevated INR with IV vitamin K and fresh frozen plasma or prothrombin concentrate complex; factor VII infusion for patients requiring urgent surgical intervention (i.e., those with cerebellar hemorrhage who are neurologically deteriorating)
- DVT prophylaxis
- Maintain oxygen saturation >94%.
- Early physical therapy and discharge planning for rehabilitation and placement
- Maintenance IV hydration with normal saline until swallowing status is assessed; monitor fluid balance closely.
- Frequent neurologic exams in first 24 hours (every 1 to 2 hours)
- Fall precautions; frequent repositioning to prevent skin breakdown
- Discharge criteria: medically stable, adequate nutritional support, neurologic status stable or improving

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Secondary prevention of stroke with aggressive management of risk factors
- Platelet inhibition using aspirin, clopidogrel, or aspirin plus extended-release dipyridamole (Aggrenox) based on physician and patient preference

Patient Monitoring
Follow-up every 3 months for 1st year and then annually

DIET
Patients with impaired swallowing should receive nasogastric or percutaneous endoscopic gastrostomy feedings to maintain nutrition and hydration.

PATIENT EDUCATION
American Stroke Association (800-STROKES or http://www.stroke.org)

PROGNOSIS
Variable depends on subtype and severity of stroke; NIH Stroke Scale may be used for prognosis.

COMPLICATIONS
- Acute: brain herniation, hemorrhagic transformation, MI, congestive heart failure, dysphagia, aspiration pneumonia, urinary tract infection, DVT, pulmonary embolism, malnutrition, pressure sores
- Chronic: falls, depression, dementia, orthopedic complications, contractures
REFERENCES

ADDITIONAL READING

CODES
ICD10
- I63.9 Cerebral infarction, unspecified
- I61.9 Nontraumatic intracerebral hemorrhage, unspecified
- I63.50 Cereb infrc due to unsp occls or stenos of unsp cereb artery

CLINICAL PEARLS
- Unless stroke is hemorrhagic or patient is undergoing thrombolysis, do not lower BP acutely. This helps to maintain perfusion of penumbra region.
- Consider IV thrombolysis in eligible patients with neurologic deficits that do not clear spontaneously within 3 to 4.5 hours of symptom onset.
- DW-MRI is more sensitive than conventional CT for the diagnosis of AIS. MRI is also superior for diagnosing posterior fossa lesions.
SUBCONJUNCTIVAL HEMORRHAGE
Nisarg Joshi, MD, BS ● Herbert J. Ingraham, MD

BASICS

DESCRIPTION

Subconjunctival hemorrhage (SCH) is bleeding from small blood vessels underneath the conjunctiva, the thin clear skin covering the sclera (white part) of the eye.

SCH is diagnosed clinically:
- Well-demarcated areas of extravasated blood can be seen just under the surface of the conjunctiva of the eye
- Lesions can be flat, elevated, or bullous.

Typically, SCH self-resolves in 1–3 weeks depending on the severity.

EPIDEMIOLOGY

- Male = female; no gender predilection
- Common; 3% rate of diagnosis in ophthalmology clinics (1)

Incidence

Incidence increases
- With increasing age
- In contact lenses wearers (5% of cases) (2)
- With systemic diseases such as diabetes, hypertension (HTN), and coagulation disorders
- With trauma
- During summer months, possibly due to trauma (1)

ETIOLOGY AND PATHOPHYSIOLOGY

Subconjunctival hemorrhage results from damage to conjunctival and episcleral vessels from direct or indirect injury.

Antithrombogenic and anticoagulated states (blood dyscrasias, thrombocytopenia, anemia, antiplatelet use, anticoagulant use) increase the risk and severity of SCH.

Causes include
- Idiopathic (most common cause)
- Direct trauma from
  - Blunt or penetrating injury to the eye
  - Contact lens placement or removal; improper contact lens wear
  - Rubbing eyes
  - Foreign body in eye
  - Ocular surgery, injection, or other procedure
- Valsalva maneuvers causing sudden severe venous congestion such as coughing, sneezing, vomiting, straining, severe asthma or COPD exacerbation, weightlifting, or childbirth/labor
- Damaged vessels from diabetes or atherosclerotic disease. Diabetes is a cause of recurrent SCH without trauma

In patients age >60 years, HTN is the most common etiology.
In patients age <40 years, trauma, Valsalva and contact lens use are the most common etiologies.
In patients age >40 years, conjunctivochalasis (redundant conjunctival folds) and presence of pinguecula are strongly associated (2).

**RISK FACTORS**
- Trauma
- Age
- Contact lens wearer
- Systemic diseases (HTN, diabetes)
- Bleeding disorders (1)
- Recent ocular surgery (cataract, laser-assisted in situ keratomileusis [LASIK])

**GENERAL PREVENTION**
- Avoid rubbing eyes
- Proper cleaning and maintenance of contact lenses
- Protective eyewear in sports and hobbies
- Optimizing control of systemic diseases such as HTN, diabetes, and atherosclerotic disease, thrombocytopenia
- Control of PT/INR in patients on warfarin therapy (3)

**DIAGNOSIS**

**HISTORY**
- Usually, the patient notices redness in the mirror or another person mentions it to the patient.
- Generally, patients do not have ocular symptoms.
- May complain of mild irritation or foreign body sensation
- Obtain history of trauma, recent ocular surgery, rubbing eyes, contact lens use, heavy Valsalva maneuvers (coughing, straining going to the bathroom, lifting heavy objects, etc.) (1). SCH can occur 12 to 24 hours after orbital fracture (4).
- Evaluate medical history of systemic disease like diabetes mellitus, hypertension, and coagulopathy
- Ask about medications that may increase risk—aspirin, clopidogrel, other antiplatelets, anticoagulants
- Obtain history of other systemic symptomatology.

**PHYSICAL EXAM**
- Visual acuity, intraocular pressure, and pupils should be unaffected (3).
- Slit lamp exam shows bright red well-demarcated spots or patches. They are more often inferior due to gravity (2).
- Lesions can be flat, elevated, or bullous.
- The color of the conjunctiva changes over time. When the blood newly accumulates, the color is bright red. Older blood has a darker red color. The conjunctiva may have a yellow hue from blood-breakdown products as the hemorrhage dissipates.
- Fluorescein can be applied to assess for conjunctival and cornea abrasions/lacerations. Under cobalt blue light, there should be no stain uptake with a simple SCH.
- If the conjunctiva was lacerated, drops of blood can extrude from the conjunctiva onto the eyelid and periorbital skin.
- If a foreign body was involved, it could be hidden by the SCH.
If there is concern for penetrating or perforating ocular trauma, a shield should be placed over the eye and the patient should be evaluated emergently by an ophthalmologist and/or trauma team.

Measure blood pressure to evaluate for uncontrolled hypertension (1).

Geriatric Considerations
In older adults, the area of SCH will be more widespread across the sclera (2). Elastic and connective tissues are more fragile with age, and underlying conditions such as HTN and diabetes may contribute.

Differential Diagnosis
- Viral, bacterial, allergic, or chemical conjunctivitis (enterovirus and coxsackievirus most common) (4)[B]
- Foreign body in/on the conjunctiva
- Penetrating or perforating trauma
- Recent ocular surgery/injection
- Contact lens–induced
- Child abuse (particularly if bilateral in an infant or toddler) (4)
- Occasionally found in newborns following vaginal delivery

Diagnostic Tests & Interpretation
- Typically no testing is indicated; SCH is a clinical diagnosis. If a foreign body is suspected, perform a fluorescein exam.
- Fluorescein exam of a patient with an SCH should show no uptake of fluorescein (3)[C].
- If an orbital fracture is suspected, an orbital/maxillofacial CT may be obtained (5)[C].

Follow-Up Tests & Special Considerations
If history and physical exam suggest a bleeding disorder (3)[C]
- CBC
- PT/INR

Alert
- If a penetrating injury is suspected, may obtain a CT scan of the orbits
- Do not perform MRI because the foreign object may be metallic (5)[C].

Treatment
- Reassurance is important.
- SCH self-resolves with time.
- Artificial tears can be used four times a day as needed for eye irritation (3)[C].

General Measures
- Control BP
- Control blood glucose
- Control INR
- Wear protective eyewear

Issues for Referral
• If there is a history of any significant trauma, even blunt trauma, seek emergent ophthalmology consultation.
• If the patient complains of any decreased visual acuity or visual disturbances (i.e., new floaters), refer to an ophthalmologist as soon as possible.
• If there is no resolution of SCH within 2 weeks or if SCH are recurrent, patient may need referral to an ophthalmologist.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
• Follow up only if the area does not resolve in about 2 weeks.
• If SCH recurs, then work up patient for systemic sources such as bleeding disorders (3)[C] or diabetes.

PATIENT EDUCATION
• Reassurance of the self-limited nature of the problem and typical time frame for resolution
• Education to return to clinic if the area does not heal or recurs
• Correct cleaning and maintenance of contact lenses
• Eye lubricants for ocular irritation

PROGNOSIS
Excellent

COMPLICATIONS
Rare

REFERENCES

ADDITIONAL READING

CODES
ICD10
- H11.30 Conjunctival hemorrhage, unspecified eye
- H11.31 Conjunctival hemorrhage, right eye
- H11.32 Conjunctival hemorrhage, left eye

CLINICAL PEARLS
- SCH is a clinical diagnosis. The condition is typically asymptomatic and will self-resolve within 2 weeks.
- Risk factors include trauma, intense Valsalva maneuvers, HTN, and diabetes.
- Indications for immediate referral to an ophthalmologist include eye pain, changes in vision, lack of pupil reactivity, and/or penetrating eye trauma.
- Reassurance and comfort measures (i.e., ocular lubrication) are mainstays of treatment.
SUBSTANCE USE DISORDERS
S. Lindsey Clarke, MD, FAAFP

BASICS

DESCRIPTION
Any pattern of substance use causing significant physical, mental, or social dysfunction
● Substances of abuse include:
  – Alcohol
  – Tobacco
  – Prescription medications
    o CNS depressants (barbiturates, benzodiazepines, hypnotics)
    o Opioids and morphine derivatives (codeine, fentanyl, hydrocodone, hydromorphone, oxymorphone [Opana], meperidine, methadone, morphine, oxycodone)
    o Stimulants (amphetamine, methylphenidate)
    o Dextromethorphan (“Robotripping”)
  – Cannabis (marijuana, hashish, cannabis oil, and extracts); increasingly sold as highly concentrated extracts (up to 90% THC) for use in vaporizers
  – Synthetic cannabinoids (Spice, K2, fake weed); often much more potent than marijuana; may be smoked, brewed in tea, or vaporized
  – Stimulants (cocaine, amphetamines, methamphetamines, Khat)
  – “Club drugs” (MDMA [ecstasy, Molly], PMMA [Superman], flunitrazepam, γ-hydroxybutyrate [GHB])
  – Opioids (heroin, opium, kratom, desomorphine [Krokodil])
  – Dissociative drugs (ketamine, phencyclidine [PCP])
  – Hallucinogens (lysergic acid diethylamide [LSD], salvia, ayahuasca, N,N-dimethyltryptamine [DMT])
  – Synthetic cathinones (bath salts, α-PVP [Flakka])
  – Inhalants (glue, paint thinners, nitrous oxide)
● Synonym(s): drug abuse; drug dependence; substance abuse

Geriatric Considerations
● Alcohol is the most commonly abused substance, and abuse often goes unrecognized.
● Higher potential for drug interactions

Pregnancy Considerations
Substance abuse may cause fetal abnormalities, morbidity, and fetal or maternal death.

ALERT
The prevalence of opioid use in pregnancy and associated neonatal abstinence syndrome has increased significantly in recent years. Screen for substance use at the first prenatal visit with a brief intervention, and refer for treatment to improve maternal and neonatal outcomes (1).

EPIDEMIOLOGY
Incidence
● Predominant age: 18 to 25 years
Predominant sex: male > female

Prevalence
- 30.5 million Americans (11.2%) reported illicit drug use in 2017.
- 7.9% of 12- to 17-year-olds; 24.2% of 18- to 25-year-olds
- 1 in 5 (22.1%) young adults currently use marijuana.

Etiology and Pathophysiology
Multifactorial, including genetic, environmental

Genetics
Substances of abuse affect dopamine, acetylcholine, γ-aminobutyric acid, norepinephrine, opioid, and serotonin receptors. Variant alleles may account for differences in susceptibility to misuse of different substances.

Risk Factors
- Male gender, young adult
- Depression, anxiety
- Other substance use disorders
- Family history
- Peer or family use or approval
- Low socioeconomic status
- Unemployment
- Accessibility of substances of abuse
- Family dysfunction or trauma
- Antisocial personality disorder
- Academic problems, school dropout
- Criminal involvement

General Prevention
- Early identification and aggressive early intervention improve outcomes.
- Universal school-based interventions are modestly effective for preventing drug use among adolescents.

Commonly Associated Conditions
- Depression
- Personality disorders
- Bipolar affective disorder

Alert
Prescription narcotic overdose is the leading cause of accidental death in patients between the ages of 25 and 44 years in the United States.

Diagnosis
Substance use disorder (DSM-5 criteria): ≥2 of the following in past year severity based on number of criteria present:
- Missed work or school
Use in hazardous situations
Continued use despite social or personal problems
Craving
Tolerance (decreased response to effects of drug due to constant exposure)
Withdrawal on discontinuation
Using more than intended
Failed attempts to quit
Increased time spent obtaining, using, or recovering from the substance
Interference with important activities
Continued use despite health problems

HISTORY
History of infections (e.g., endocarditis, hepatitis B or C, TB, STI, or recurrent pneumonia)
Social or behavioral problems, including chaotic relationships and/or employment difficulties
Frequent visits to emergency department
Criminal incarceration
History of blackouts, insomnia, mood swings, chronic pain, repetitive trauma
Anxiety, fatigue, depression, psychosis

PHYSICAL EXAM
Vital sign abnormalities (changes in HR, RR, BP, and temperature all manifest with substance misuse)
Abnormally dilated or constricted pupils
Cutaneous needle marks
Nasal septum perforation (with cocaine use)
Cardiac dysrhythmias, pathologic murmurs
Malnutrition with severe dependence
Mental status examination

DIFFERENTIAL DIAGNOSIS
Depression, anxiety, or other behavioral conditions
Metabolic delirium (hypoxia, hypoglycemia, infection, thiamine deficiency, hypothyroidism, thyrotoxicosis)
ADHD
Medication toxicity

DIAGNOSTIC TESTS & INTERPRETATION

ALERT
Screening with a single question: “How many times in the past year have you used an illegal drug or used a prescription medication for nonmedical reasons?”: has a sensitivity of 100% and specificity of 74% in primary care setting (2)[B]

CRAFFT questionnaire (sensitivity 94% with ≥2 “yes” answers):
- C: Have you ever ridden in a CAR driven by someone (including yourself) who was “high” or who had been using alcohol or drugs?
- R: Do you ever use alcohol or drugs to RELAX, feel better about yourself, or fit in?
- A: Do you ever use alcohol or drugs while you are ALONE?
- F: Do you ever FORGET things you did while using alcohol or drugs?
– F: Do your FAMILY or FRIENDS ever tell you that you should cut down on your drinking or drug use?
– T: Have you gotten into TROUBLE while you were using alcohol or drugs?

● American Academy of Pediatrics also recommends the following brief screening tools for adolescents (3):
  – S2B1 (Screening to Brief Intervention)
  – BSTAD (Brief Screener for Tobacco, Alcohol, and Other Drugs)
● Blood alcohol concentration
● Urine drug screen (UDS) (order qualitative UDS, and if specific drug is in question, a quantitative analysis for specific drug; order confirmatory serum tests if false positive suspected)

● Approximate detection limits
  – Alcohol: 6 to 10 hours
  – Amphetamines and variants: 2 to 3 days
  – Barbiturates: 2 to 10 days
  – Benzodiazepines: 1 to 6 weeks
  – Cocaine: 2 to 3 days
  – Heroin: 1 to 1.5 days
  – LSD, psilocybin: 8 hours
  – Marijuana: 1 to 7 days; up to 1 month with chronic/heavy use
  – Methadone: 1 day to 1 week
  – Opioids: 1 to 3 days
  – PCP: 7 to 14 days
  – Anabolic steroids: oral, 3 weeks; injectable, 3 months; nandrolone, 9 months
● Liver transaminases
● HIV, hepatitis B and C screens
● Echocardiogram for endocarditis
● Head CT scan for seizure, delirium, trauma

🔍 **TREATMENT**

Determine substances abused early (may influence disposition).

**GENERAL MEASURES**
● Nonjudgmental, medically oriented attitude
● Motivational interviewing and brief interventions can overcome denial and promote change.
● Behavioral and cognitive therapy
● Community reinforcement
● Intervenotional counseling
● Self-help groups to aid recovery (Alcoholics Anonymous, other 12-step programs)
● Support groups for family (Al-Anon/Alateen)

**MEDICATION**
● Alcohol withdrawal: See “Alcohol Use Disorder (AUD)” and “Alcohol Withdrawal.”
● Benzodiazepine or barbiturate withdrawal
  – Gradual taper preferable to abrupt discontinuation
– Substitution of long-acting benzodiazepine (e.g., clonazepam) or phenobarbital

Nicotine withdrawal: See “Tobacco Use and Smoking Cessation.”

**Opioid dependence**

– Buprenorphine: 8 to 24 mg SL daily, 100 to 300 mg SC monthly, or as 6-month subdermal implant; may precipitate a more severe withdrawal if initiated too soon; use restricted to licensed clinics and certified physicians (4,5,6)[A].

– Buprenorphine/naloxone: 2/0.5 mg to 16/4 mg SL daily; available as SL tabs and films and buccal films; combination limits abuse potential compared with buprenorphine alone.

– Methadone: 10 to 40 mg/day PO; use restricted to inpatient settings and especially licensed clinics (4,5,6)[A].

– Naltrexone: 50 mg PO daily, 100 mg PO every 2 days, 150 mg PO every 3 days, or 380 mg IM every 4 weeks; must be opioid-free for 7 to 10 days prior to treatment to avoid precipitating withdrawal

**Opioid withdrawal**

– Clonidine: 0.1 to 0.2 mg PO BID or TID for autonomic hyperactivity (7)[A]

**Stimulant withdrawal**

– No agent with clear benefit

– Methylphenidate ER: titrated up to 54 mg/day PO might enhance abstinence in amphetamine-dependent patients

**Adjuncts to therapy**

– Use all medications in conjunction with psychosocial behavioral interventions.

– Antiemetics, nonaddictive analgesics for opioid withdrawal

– Nonhabituating antidepressants, mood stabilizers, anxiolytics, and hypnotics for comorbid mood and anxiety disorders and insomnia that persist after detoxification

**Contraindications**

– Buprenorphine in breastfeeding, hepatic impairment

– Methadone in hepatic impairment

– Naltrexone in pregnancy, breastfeeding, hepatic impairment

**Precautions:** Clonidine can cause hypotension.

**Significant possible interactions**

– Buprenorphine and opioids, CNS depressants, or HIV protease inhibitors

– Methadone and strong inhibitors of CYP3A4 (clarithromycin, ketoconazole, HIV protease inhibitors), opioids, CNS depressants

– Naltrexone and opioid medications (may induce or exacerbate withdrawal)

**ISSUES FOR REFERRAL**

– Consider addiction specialist, especially for opioid and polysubstance abuse.

– Maintenance therapy for opioid dependence (e.g., methadone) only in FDA-licensed clinics

– Psychiatrist for comorbid psychiatric disorders

– Social services

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

– Indications for inpatient detoxification

  – History of severe withdrawal (e.g., seizures)

  – Mental status changes

  – Hallucinations or psychotic features

  – Threat of harm to self or others
– Obstacles to close monitoring/follow-up
– Comorbid medical illness
– Pregnancy
• Consider specialist referral for narcotic addiction and withdrawal.
• Look for signs of severe infection (e.g., bacterial endocarditis).
• Frequently check vital signs during withdrawal.
• Monitor for signs of drug use in the hospital.
• Discharge criteria
  – Detoxification complete
  – Rehabilitation plan in place

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Initially frequent visits to monitor for medical stability and adherence and then progressive follow-up intervals

**Patient Monitoring**
Verify patient’s adherence with the substance abuse treatment program.

**DIET**
Patients often are malnourished.

**PATIENT EDUCATION**
• Substance Abuse and Mental Health Services Administration: [https://www.samhsa.gov](https://www.samhsa.gov) or 800-662-HELP (4357) for information, treatment facility locator
• National Institute on Drug Abuse: [http://www.drugabuse.gov/patients-families](http://www.drugabuse.gov/patients-families)
• Alcoholics Anonymous: [http://www.aa.org](http://www.aa.org)
• Narcotics Anonymous: [http://www.na.org](http://www.na.org)

**PROGNOSIS**
• Patients in treatment for longer periods have higher success rates.
• Behavioral therapy and pharmacotherapy are most successful when used in combination.

**COMPLICATIONS**
• Serious harm to self and others: accidents, violence
• Overdoses resulting in seizures, arrhythmias, cardiac and respiratory arrest, coma, death
• Hepatitis, HIV, tuberculosis, syphilis
• Subacute bacterial endocarditis
• Malnutrition
• Social problems, including arrest
• Poor marital adjustment and violence
• Depression, schizophrenia
• Sexual assault (alcohol, flunitrazepam, GHB)

**REFERENCES**

Alcohol Use Disorder (AUD); Alcohol Withdrawal; Tobacco Use and Smoking Cessation

CODES

ICD10

- F19.10 Other psychoactive substance abuse, uncomplicated
- F10.10 Alcohol abuse, uncomplicated
- F12.10 Cannabis abuse, uncomplicated

CLINICAL PEARLS

- Substance use disorders are prevalent, serious, and often unrecognized in clinical practice. Comorbid psychiatric disorders are common.
- Substance abuse is distinguished by family, social, occupational, legal, or physical dysfunction that is caused by persistent use of the substance.
- Dependence is characterized by tolerance, withdrawal, compulsive use, and repeated overindulgence.
- Motivational interviewing, brief interventions, and a nonjudgmental attitude help to promote a willingness to change behavior.
- Consider referring patients with alcohol or opioid dependence to an addiction specialist or treatment program.
SUICIDE
Irene Coletsos, MD ● Harold J. Bursztajn, MD

BASICS

DESCRIPTION
Suicide and attempted suicide are significant causes of morbidity and mortality.

EPIDEMIOLOGY

● Predominant sex
  – Women attempt suicide 1.5 times more often than men. Men complete suicide 3 times more often than women. Men are more likely to choose a means with high lethality, such as firearms.

● Predominant age: adolescent (2nd leading cause of death), 10th leading cause of death overall

● Marital status: single > divorced; widowed > married

● Worldwide, suicide is the 18th leading cause of death and the 2nd leading cause of death among youths (ages 15 to 29 year olds).

Incidence
In 2016, 10th leading cause of death in adults in the United States. Military service (not specifically active duty) is associated with increased risk. A 2017 Veterans Administration study reported that veterans had a 22% increased rate of suicide over civilians (1).

RISK FACTORS

● “Human understanding is the most effective weapon against suicide. The greatest need is to deepen the awareness and sensitivity of people to their fellow man” (2).

● Be alert to a combination of “perturbation” (increased emotional disturbance) and “lethality” (having the potential tools to cause death).

● 80% who complete suicide had a previous attempt.

● 90% who complete suicide meet Diagnostic and Statistical Manual criteria for Axis I or II disorders: major depression, bipolar disorder, anorexia nervosa, panic disorder, and borderline and antisocial personality disorders. Schizophrenia or acute onset of psychosis is also a risk factor due to command hallucinations or even the negative affect or hopelessness that can accompany these states.

● Substance use and withdrawal (alcohol, hallucinogens, opioids)

● Family history of suicide

● Physical illness, including head injury (TBI associated with 20% increased risk of death by suicide) (2).

● Despair: emotional pain and without hope and, consciously or unconsciously, unworthy of help

● Among teenagers: not feeling “connected” to their peers or family; being bullied; gender identity issues; poor grades

● Among veterans: childhood history of abuse; a diagnosis of major depressive disorder and multiple inpatient psychiatric admissions were found to be the “best predictors of enhanced suicide risk” (1).

● Psychosocial: recent loss. What may seem to be a small loss (to a medical provider) may be a devastating loss to the patient. Patient-specific factors need to be taken into account: social
isolation, anniversaries, and holidays. Patients who attempt suicide also seem to have impaired decision-making skills and risk awareness and increased impulsivity compared with patients who have never attempted suicide (3).

- If a patient is incompetent (e.g., too delusional) to alert providers about the potential for suicide, the patient is at increased risk for self-harm and providers should consider hospitalization.
- Access to lethal means: firearms, poisons (including prescription and nonprescription drugs; pesticides); common method of self-harm in developing countries

**GENERAL PREVENTION**

- Know how to access resources 24/7 within and outside of the health care institution.
- Screen for risk: Use screening instruments but keep in mind risks particular to each patient, which could lead to increased risks not captured in some screening tools. Screening instruments include the Patient Health Questionnaire-2 (PHQ-2), the PHQ-9, the Columbia Suicide Severity Rating Scale, Beck Scale for Suicide Ideation, Linehan Reasons for Living Inventory, and Risk Estimator for Suicide.
- Treat underlying mental and medical illnesses and substance abuse.
- Screen for possession of means of harm, including prescribed/unprescribed drugs, poisons, and firearms (encourage the removal of guns from the home and the relinquishment of gun licenses).
- Create a safety plan for patients at risk for suicide and their families, including education about how to access emergency care 24 hours a day.
- Public education about how to help others access emergency psychiatric care. Suicidal people may initially confide in those they trust outside health care (e.g., family members, religious leaders, “healers,” or retail service providers such as hairdressers and bartenders).
- Law enforcement education through the FBI’s National Center for Analysis of Violent Crime in recognizing and triaging potential “suicide by cop” events (deliberate attempt to trigger lethal force); thought to be responsible for approximately 20% of fatal police shootings in the United States between 1998 and 2006 (2)
- For the military: multiple resources: http://www.realwarriors.net. Suggested treatments include cognitive restructuring techniques (that their experience with adversity can be a source of strength) and help with problem solving (so the service member does not feel like a “burden”), therapeutic martial arts training, focus on vets’ helping others: “Power of 1” initiative (any “one” helpful contact could save a life).
- In developing world countries, pesticide ingestion is a common method of suicide. Limiting free access has led to reduced suicide rates.

**DIAGNOSIS**

**HISTORY**

- Depressed patients should be asked about suicidal ideation and a potential plan:
  - “Have you ever felt that life isn’t worth living? Do you ever wish you could go to sleep and not wake up? Are you having thoughts about killing yourself?”
- Use psychodynamic formulation, which combines mental-state exam (i.e., behavior, mood, mental content, judgment), past history (i.e., What resources has the patient used in the past for support, and are they currently available?), and history of current illness. If the patient is
experiencing a loss or is under stress and does not have access to a previously sustaining resource (e.g., a significant other, a pet, sports ability, a job), that patient is at increased risk for suicide.

- Prior attempts: precipitants, lethality, intent to die, precautions taken to avoid being rescued, reaction to survival (a patient who is upset that the suicide was not completed is at increased risk for a subsequent attempt)
- History of psychiatric symptoms, substance abuse
- Also note strengths, such as reasons to live, hopes for future, social supports. A patient without these is at increased risk.
- Gather collateral history (from friends, family, physicians). It is appropriate to break confidentiality if patient is at imminent risk of suicide.

**PHYSICAL EXAM**

- Medical conditions: delirium, intoxication, withdrawal, medication side effects
- Psychosis: Observe for signs of/ask about command auditory hallucinations to kill oneself, delusional guilt, and persecutory delusions.
- In adults: Observe for signs of hopelessness/despair (see “Risk Factors”).
- In teens: may not appear to be depressed; therefore, screen for risk factors such as substance abuse, bullying and social isolation (commonly through electronic media), and poor grades.

**DIFFERENTIAL DIAGNOSIS**

Suicidal threats and gestures need to be immediately triaged to assess patient safety, although in some cases the threat could be an attempt to manipulate others, such as in the case of personality disorders.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Diagnostic Procedures/Other**

Brief tests that could be part of any medical/mental health assessment:

- PHQ-9: [http://www.med.umich.edu/1info/FHP/practiceguides/depress/score.pdf](http://www.med.umich.edu/1info/FHP/practiceguides/depress/score.pdf)
- Suicide Trigger Scale version 3, (STS-3), which measures a patient’s “ruminative flooding” (self-critical, repetitive thoughts) and “frantic hopelessness” (feeling trapped, suicide is the only choice): [http://www.ncbi.nlm.nih.gov/pmc/articles/PMC3443232/](http://www.ncbi.nlm.nih.gov/pmc/articles/PMC3443232/)

**TREATMENT**

**GENERAL MEASURES**

- Patients expressing active suicidal thoughts or who made an attempt require immediate evaluation for risk factors, mental status, and capacity (to determine if they are able/willing to inform treaters about suicidal intentions) as well as a formal psychiatric consultation.
- Cognitive therapy decreased reattempt rate in prior suicide attempters by half. (i) Establish therapeutic alliance. Have patient tell a story about recent suicidal thought or action. (ii) Help patient develop the skills needed to deal with the thoughts or feelings that trigger suicidal crises. (iii) Have patient imagine being in the situation that brought on the earlier crisis, but this time, guide that patient to practice problem-solving strategies—reinforcing the use of coping skills, rather than suicidal actions (4,5).
- Psychotherapy with suicidal patients is a challenge even for the most experienced clinicians.
The countertransference, a clinician’s feelings toward a patient, can evolve into wanting to be
rid of the patient. If the patient detects this, the risk of suicide is heightened. The clinician can
avoid this by recognizing countertransference and bearing it within so that the patient remains
unaware (6).

- Among military personnel: ACE campaign: **Ask about suicidal thoughts; Care for the person,**
  including removing access to lethal weapons; **Escort** the soldier/vet to help: an emergency
  room, a 911 call; call to a support hotline such as (800) 273-TALK (8255); text: 838255.

**MEDICATION**

- Psychopharmacology “is not a substitute for getting to know the patient” (7).
- Patients are at increased risk of suicide at the outset of antidepressant treatment and when it is
discontinued. Consider tapering/switching medical therapies rather than sudden
discontinuation. Monitor carefully at these times.
- Anxiety, agitation, and delusions increasing in intensity are risk factors for suicide and should
  be treated aggressively.
- In patients with mood disorders, a meta-analysis of randomized, controlled trials found that
  lithium reduced the risk of death by suicide by 60% (7)[A].
- Agitated or combative patients may require sedation with IV or IM benzodiazepines and/or
  antipsychotics. Clinical response is typically seen within 20 to 30 minutes if given IM/IV.

**Pediatric Considerations**

FDA posted black box warning for antidepressant use in the pediatric population after increased
suicidality was noted. If risk of untreated depression is sufficient to warrant treatment with
antidepressants, treat but monitor for suicidality.

**First Line**

ECGs before prescribing or continuing antidepressants or antipsychotics to look for QT
prolongation

**ISSUES FOR REFERRAL**

Consider a psychiatric consult. All decisions regarding treatment must be carefully documented
and communicated to all involved health care providers.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Inpatient hospitalization if patient is suicidal with a plan to act or is otherwise at high risk; if
  immediate risk for self-harm, may be hospitalized involuntarily
- Immediately after a suicide attempt, treat the medical problems resulting from the self-harm
  before attempting to initiate psychiatric care.
- Order lab work (e.g., solvent screen, blood and urine toxicology screen, aspirin and
  acetaminophen levels). Patients may not disclose ingestions if they wish to succeed in their
  attempt or if they are undergoing mental status changes.
- Risk for self-harm continues even in the hospital. As soon as patients arrive at a hospital, they
  should be searched and potentially dangerous objects removed; they should be under one-to-
one constant observation, offered medication to ease symptoms; mechanical restraints only if
  necessary for patient safety
- The period after transfer from involuntary to voluntary hospitalization and postdischarge are
times of high risk.
- Discharge criteria
– No longer considered a danger to self/others
– Clinicians should be aware that a patient may claim that he or she is no longer suicidal in order to facilitate discharge—and complete the act. Look for clinical and behavioral signs that the patient truly is no longer in despair and is hopeful, such as improved appetite, sleep, engagement with staff and group therapy. Clinicians should check with family and ancillary staff because patients may share more information with them than with doctors.
– Provide information about 24/7 resources.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Increase monitoring at the beginning of treatment, when changing medications, and on discharge.
- Educate family members and other close contacts/confidants to the warning signs of suicidality. For adults, despair/hopelessness, isolation, discussing suicide, stating that the world would be a “better place” without them, losses in areas key to the patient’s self-worth. For youths, may exhibit the same signs and symptoms, but one should be aware of these additional risks: history of abuse (e.g., sexual, physical), bullying in person or via electronic media (e.g., text messages or social media), family stress, changes in eating and sleeping patterns, suicidality of friends, and giving away treasured items.
- Make sure that the patient is willing to accept the type of follow-up offered. Do not assume that just setting it up is sufficient protection.
- Curtail access to firearms.
- Limiting the number of pills may be appropriate for an impulsive patient. However, clinicians may believe that by simply limiting the number of pills they prescribe, they are preventing further suicide attempts, an example of “magical thinking.” Clinicians who find themselves thinking this way can take it as a warning sign that their patients may actually be at increased risk of suicide.

**PATIENT EDUCATION**

Patients who feel they are in danger of hurting themselves should consider one or several of these options:

- Call 911.
- Go directly to an emergency room.
- If already in counseling, contact that therapist immediately.
- Call the National Suicide Prevention Hotline at (800) 273-TALK (8255).
- Servicemen and servicewomen and their families can call (800) 796-9699; if there is no immediate answer, call (800) 273-TALK (8255); text 838255.

**PROGNOSIS**

The key to a favorable prognosis is early recognition of risk factors, early diagnosis and treatment of a psychiatric or medical disorder (leading to distress), and appropriate intervention and follow-up.

**COMPLICATIONS**
According to the American Association of Suicidology (AAS) the grief process for significant others of suicide victims can be lifelong and can be expressed in emotions ranging from anger to despair. Survivors often attempt to shoulder the burden on their own because of the added guilt and shame of the nature of the attempted death or death.

The AAS recommends the following:
- Counseling: could include short-term behavioral therapy as well as psychotherapy; some therapy should focus on the survivors’ relationships to their current and future significant others. Survivors often seek out life partners as “replacements” for those they lost—could interfere with mourning.
- Sympathetic listening by friends
- Support during holidays

REFERENCES

ADDITIONAL READING

CODES
ICD10
R45.851 Suicidal ideations
T14.91 Suicide attempt
Z91.5 Personal history of self-harm

**CLINICAL PEARLS**

- Key preventative measure is to listen to a patient and take steps to keep him or her safe. This could include immediate hospitalization. Questions to explore include “Are you thinking of killing yourself?” “Who do you have to live for?” and “What should change so that you could live with your suffering?”
- Clozapine, lithium, and CBT are associated with a reduction in the risk of suicide.
- Family and contacts of people who have attempted or committed suicide suffer from reactions ranging from rage to despair. Encourage counseling.
- Resources for clinicians: [https://www.suicidology.org/](https://www.suicidology.org/); [https://www.suicideassessment.com](https://www.suicideassessment.com)
SUPERFICIAL THROMBOPHLEBITIS
Emily M. Culliney, MD, FAAFP

BASICS

DESCRIPTION

- Superficial thrombophlebitis is venous inflammation with secondary thrombosis of a superficial vein.
- Most common in the lower extremities (60–80%) but can occur in the upper extremities/neck.
- Generally a benign and self-limiting process but can be painful.
- Traumatic thrombophlebitis types:
  - Injury
  - IV catheter related
  - Intentional (i.e., sclerotherapy)
- Aseptic thrombophlebitis types:
  - Primary hypercoagulable states: disorders with measurable defects in the proteins of the coagulation and/or fibrinolytic systems
  - Secondary hypercoagulable states: clinical conditions with a risk of thrombosis (venous stasis, pregnancy)
- Septic (suppurative) thrombophlebitis types:
  - Iatrogenic, long-term IV catheter use
  - Infectious, mainly syphilis and psittacosis
- Mondor disease
  - Rare presentation of anterior chest/breast veins of women
- System(s) affected: cardiovascular
- Synonym(s): phlebitis; phlebothrombosis

Geriatric Considerations

Septic thrombophlebitis is more common; prognosis is poorer.

Pediatric Considerations

Subperiosteal abscesses of adjacent long bone may complicate the disorder.

Pregnancy Considerations

- Associated with increased risk of aseptic superficial thrombophlebitis, especially during postpartum.
- NSAIDs are contraindicated during pregnancy.

EPIDEMIOLOGY

- Predominant age
  - Traumatic/IV related has no predominant age/sex.
  - Aseptic primary hypercoagulable state
    - Childhood to young adult
- Aseptic secondary hypercoagulable state
  - Mondor disease: women, ages 21 to 55 years
  - Thromboangiitis obliterans onset: ages 20 to 50 years
Predominant sex
- Suppurative: male = female
- Aseptic
  - Spontaneous formation: female (55–70%)
  - Mondor: female > male (2:1)

Incidence
- Septic
  - Incidence of catheter-related thrombophlebitis is 88/100,000 persons per year.
  - Develops in 4–8% if cutdown is performed
- Aseptic primary hypercoagulable state: Antithrombin III and heparin cofactor II deficiency incidence is 50/100,000 persons.
- Aseptic secondary hypercoagulable state
  - In pregnancy, 49-fold increased incidence of phlebitis
  - Superficial migratory thrombophlebitis in 27% of patients with thromboangiitis obliterans

Prevalence
- Superficial thrombophlebitis is common.
- 1/3 of patients in a medical intensive care unit (ICU) develop thrombophlebitis that eventually progresses to the deep veins.

ETIOLOGY AND PATHOPHYSIOLOGY
- Similar to deep venous thrombosis (DVT); virchow triad of vessel trauma, stasis, and hypercoagulability (genetic, iatrogenic, or idiopathic)
- Varicose veins play a primary role in etiology of lower extremity phlebitis.
- Mondor disease pathophysiology not completely understood
- Less commonly due to infection (i.e., septic)
  - Staphylococcus aureus, Pseudomonas, Klebsiella, Peptostreptococcus sp.
  - Candida sp.
- Aseptic primary hypercoagulable state
  - Due to inherited disorders of hypercoagulability
- Aseptic secondary hypercoagulable states
  - Malignancy (Trousseau syndrome: recurrent migratory thrombophlebitis): most commonly seen in metastatic mucin or adenocarcinomas of the gastrointestinal tract (pancreas, stomach, colon, and gallbladder), lung, prostate, and ovary
  - Pregnancy
  - Estrogen-based oral contraceptives
  - Behçet, Buerger, or Mondor disease

Genetics
Not applicable other than hypercoagulable states

RISK FACTORS
- Nonspecific
  - Varicose veins
  - Immobilization
  - Obesity
  - Advanced age
– Postoperative states
  • Traumatic/septic
    – IV catheter (plastic > coated)
    – Lower extremity IV catheter
    – Cutdowns
    – Cancer, debilitating diseases
    – Burn patients
    – AIDS
    – IV drug use
  • Aseptic
    – Pregnancy
    – Estrogen-based oral contraceptives
    – Surgery, trauma, infection
    – Hypercoagulable state (i.e., factor V, protein C, or S deficiency, others)
  • Thromboangiitis obliterans: persistent smoking
  • Mondor disease
    – Breast cancer or breast surgery

GENERAL PREVENTION
  • Avoid lower extremity cannulations/IV.
  • Insert catheters under aseptic conditions, secure cannulas, and replace every 3 days.
  • Avoid stasis and use usual DVT prophylaxis in high-risk patients (i.e., ICU, immobilized).

COMMONLY ASSOCIATED CONDITIONS
  • Frequently seen with concurrent DVT (6–53%) 
  • Symptomatic pulmonary embolism (PE) can also be seen concurrently (0–10%).
  • Both DVT/PE can occur up to 3 months after onset of phlebitis.

DIAGNOSIS

HISTORY
Pain along the course of a vein

PHYSICAL EXAM
  • Swelling, tenderness, redness along the course of a vein or veins
  • May have a palpable cord along the course of the vein
  • May look like localized cellulitis or erythema nodosum
  • Fever in 70% of patients in septic phlebitis
  • Sign of systemic sepsis in 84% of suppurative cases

DIFFERENTIAL DIAGNOSIS
  • Cellulitis
  • DVT
  • Erythema nodosum
  • Cutaneous polyarteritis nodosa
  • Lymphangitis
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Often none necessary if afebrile, otherwise healthy
- Small or distal veins (i.e., forearms or below the knee): no recommended imaging
- If concern for more proximal extension: venous Doppler ultrasound (US) to assess extent of thrombosis and rule out DVT (1)[A]

Follow-Up Tests & Special Considerations
- If suspicious for sepsis
  - Blood cultures (bacteremia in 80–90%)
  - Consider culture of the IV fluids being infused.
  - Complete blood count demonstrates leukocytosis.
- Aseptic: evaluation for coagulopathy if recurrent or without another identifiable cause (e.g., protein C and S, lupus anticoagulant, anticytoplasmic antibody, factor V and VIII, homocysteine)
- In migratory thrombophlebitis, have a high index of suspicion for malignancy.
- Repeat venous ultrasound to assess effectiveness of therapy.
  - If thrombosis is extending, more aggressive therapy required.

Test Interpretation
The affected vein is enlarged, tortuous, and thickened with endothelial damage and necrosis.

TREATMENT

GENERAL MEASURES
- Suppurative: consultation for urgent surgical venous excision
- Local, mild (2)[C]
  - Conservative management, antibiotics not useful
  - For varicosities
    - Compression stockings; maintain activities.
    - Catheter/trauma associated
      - Immediately remove IV and culture tip.
      - Elevate with application of warm compresses.
      - If slow to resolve, consider low-molecular-weight heparin (LMWH).
- Large, severe, or septic thrombophlebitis
  - Inpatient care or bed rest with elevation and local warm compress
  - When the patient is ambulating, then start compression stockings or Ace bandages.

MEDICATION

First Line
- Best medication(s) and duration of treatment are not well-defined (1)[A].
- Localized, mild thrombophlebitis (usually self-limited)
  - NSAIDs and ASA for inflammation/pain to reduce symptoms and local progression
  - Use of compression stockings can also provide symptomatic relief (3).

Second Line
- Septic/suppurative
  - May present or be complicated by sepsis
  - Requires IV antibiotics (broad spectrum initially) and anticoagulation
- Increasing evidence shows that LMWH/fondaparinux treatment can prevent extension of superficial venous thrombosis in addition to venous thromboembolism (VTE) prevention.
  - Consider if thrombus is large, close to the junction with deep veins, or involves the long saphenous vein
    - To prevent VTE, 4 weeks of LMWH, such as enoxaparin
    - 45 days of fondaparinux was found to reduce DVT and VTE by 85% (relative risk reduction) in one large study (4)[B].
- Superficial thrombophlebitis related to inherited or acquired hypercoagulable states is addressed by treating the related disease.

**ISSUES FOR REFERRAL**
Severely inflamed or very large phlebitis should be evaluated for excision.

**SURGERY/OTHER PROCEDURES**
- Septic
  - Surgical consultation for excision of the involved vein segment and involved tributaries
  - Drain contiguous abscesses.
  - Remove all associated cannula and culture tips.
- Aseptic: Manage underlying conditions.
  - Evaluate for saphenous vein ligation to prevent deep vein extension after acute phase resolved.
  - Consider referral for varicosity excision.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Septic: inpatient
- Aseptic: outpatient

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Septic: routine white blood cell count and differential. Target treatment based on culture results.
- Severe aseptic
  - Repeat venous Doppler US in 1 to 2 weeks to ensure no DVT and assess treatment effectiveness: Do not expect resolution, just nonprogression.
  - Repeat clotting studies.
- Local, mild thrombophlebitis typically resolves with conservative therapy and does not require specific monitoring unless there is a failure to resolve.

**DIET**
No restrictions

**PATIENT EDUCATION**
Review local care, elevation, and use of compression hose for acute treatment and prevention of recurrence.

PROGNOSIS
- Septic/suppurative
  - High mortality (50%) if untreated
  - Depends on treatment delay or need for surgery
- Aseptic
  - Usually benign course; recovery in 2 to 3 weeks
  - Depends on development of DVT and early detection of complications
  - Aseptic thrombophlebitis can be isolated, recurrent, or migratory.
  - Recurrence likely if related to varicosity or if severely affected vein not removed.

COMPLICATIONS
- Septic: systemic sepsis, bacteremia (84%), septic pulmonary emboli (44%), metastatic abscess formation, pneumonia (44%), subperiosteal abscess of adjacent long bones in children
- Aseptic: DVT (6–53%), VTE (up to 10%), thromboembolic phenomena

SEE ALSO
Deep Vein Thrombophlebitis
CODES

ICD10
- I80.9 Phlebitis and thrombophlebitis of unspecified site
- I80.00 Phlbts and thrombophlb of superfic vessels of unsp low extrm
- I80.8 Phlebitis and thrombophlebitis of other sites

CLINICAL PEARLS
- Mild superficial thrombophlebitis is typically self-limiting and responds well to conservative care.
- Lower extremity disease involving large veins or proximal saphenous vein may benefit from anticoagulation to prevent DVT.
- Septic thrombophlebitis requires admission for antibiotics and anticoagulation. If severe, consider surgical consultation for venous excision.
SYNCOPE
Santiago O. Valdes, MD, FAAP • Emily R. Backes, MD, MA

BASICS

DESCRIPTION
- Transient loss of consciousness characterized by unresponsiveness, loss of postural tone, and spontaneous recovery; usually brief and caused by cerebral hypoperfusion
- System(s) affected: cardiovascular, nervous

EPIDEMIOLOGY

Incidence
- Overall incidence is 6.2/1,000 patient-years.
- Annual incidence of fainting spells resulting in medical evaluation was 9.5/1,000 inhabitants.
- Accounts for 1–3% of emergency room visits and 1% of hospital admissions
- There is an increased incidence after the age of 70 years, and annual incidence in institutionalized elderly (>75 years of age) is 7%.

Prevalence
- Approximately 20% of adults report ≥1 episode during their lifetime; 15% of children <18 years of age
- The prevalence in institutionalized elderly (>75 years of age) is 23%.

ETIOLOGY AND PATHOPHYSIOLOGY

- Systemic hypotension secondary to decreased cardiac output and/or systemic vasodilation leads to a drop in cerebral perfusion and resultant loss of consciousness.
- Cardiac
  - Obstructions to outflow
    o Aortic stenosis
    o Hypertrophic cardiomyopathy: most common cause of sudden cardiac death during exercise in young athletes
    o Pulmonary embolus
    o Pulmonary hypertension
  - Cardiac arrhythmias
    o Sustained ventricular tachycardia (VT)
    o Supraventricular tachycardia (SVT) (atrial fibrillation, atrial flutter, reentrant SVT)
    o Torsades de pointes (TdP)
    o Bradyarrhythmia
      ■ 2nd- and 3rd-degree atrioventricular (AV) block
      ■ Sick sinus syndrome
- Noncardiac
  - Reflex-mediated vasovagal (neurally mediated syncope [NMS]/neurocardiogenic): inappropriate vasodilation leading to neurally mediated systemic hypotension and decreased cerebral blood flow, situational (micturition, defecation, cough, pain, emotions, hair combing)
  - Orthostatic hypotension (OHT): Consider volume depletion, pregnancy, anemia,
medications.

- Drug/alcohol induced
- Primary autonomic failure: pure autonomic failure, Parkinsonism
- Secondary autonomic failure: diabetes, amyloidosis
- Carotid sinus hypersensitivity

- NMS is most common cause in adult cases.
- Vast majority of pediatric cases represent benign alterations in vasomotor tone.
- Strokes, seizures, and psychogenic nonepileptic seizures may mimic syncope but are a distinct diagnosis.

**Genetics**
Specific cardiomyopathies and arrhythmias may be inherited (e.g., long QT syndrome, catecholaminergic polymorphic VT, Brugada syndrome, hypertrophic cardiomyopathy). Primary and secondary autonomic failure syndromes and NMS may also have genetic links.

**RISK FACTORS**
- Heart disease (acquired or structural)
- Dehydration
- Drugs
  - Antihypertensives
  - Vasodilators (including calcium channel blockers, ACE inhibitors, and nitrates)
  - Phenothiazines
  - Antidepressants
  - Antiarrhythmics
  - Diuretics

**GENERAL PREVENTION**
See “Risk Factors.”

**COMMONLY ASSOCIATED CONDITIONS**
See “Etiology and Pathophysiology.”

**DIAGNOSIS**

**HISTORY**
- Careful history, physical exam, and an ECG are more important than other investigations in determining the diagnosis (1).
- Make sure that the patient or witness (if present) is not talking about vertigo (i.e., sense of rotary motion, spinning, and whirling), seizure, or causes of fall without loss of consciousness. Onset of syncope is usually rapid, and recovery is spontaneous, rapid, and complete. Duration of episodes is typically brief (<60 seconds).
- Circumstances: Prolonged standing, urination, coughing, defecation, postprandial, and intense emotions are more likely to be associated with NMS. Consider carotid sinus hypersensitivity with abrupt neck movements. Exertional syncope considers cardiac.
- Number of previous episodes: Benign causes of syncope tend to be associated with a single episode.
- Presence of prodromal symptoms: Consider NMS.
- Elderly patients less likely to experience a prodrome
- Palpitations: Consider cardiac.
- Position (supine: arrhythmia; erect: NMS, supine → erect: orthostatic hypotension)
- Prolonged syncope: Consider psychiatric and neurologic.
- Delayed recovery: Consider neurologic (postictal).
- Ask for family history of long QT syndrome, implantable cardioverter-defibrillator (ICD), hypertrophic cardiomyopathy, or unexplained sudden cardiac death in young family members.
- High-risk findings: new onset chest discomfort, breathlessness, abdominal pain, headache, syncope during exertion or when supine, or sudden palpitations immediately followed by syncope
- Even after careful evaluation, including diagnostic procedures and special tests, the cause will be found in only 50–60% of patients.

**PHYSICAL EXAM**
Check for orthostasis:
- Measure the blood pressure and pulse (BP and P) after the patient is supine for 5 minutes, then have the patient stand and repeat BP and P immediately, after standing 1 and 3 minutes (2).
- A drop in Sys BP of ≥20 mm Hg, or Dys BP of ≥10 mm Hg, or experiencing lightheadedness or dizziness is considered abnormal.
- Check for cardiac murmur or focal neurologic abnormality.
- High-risk findings: unexplained systolic BP <90 mm Hg, suggestion of gastrointestinal bleed on rectal exam, persistent bradycardia (<40 bpm) in absence of physical training, or undiagnosed systolic murmur

**DIFFERENTIAL DIAGNOSIS**
- Drop attacks
- Coma
- Vertigo
- Seizure disorder
- Stroke/transient ischemic attacks (TIAs)
- Psychiatric (conversion, somatization): lack hemodynamic and/or autonomic changes

**DIAGNOSTIC TESTS & INTERPRETATION**
- Goal is to identify life-threatening conditions or those associated with significant risk of injury (3).
- Comprehensive medical and family history, physical examination, and ECG should guide future testing (3).
- No one single test defines the cause of syncope (3).

**Initial Tests (lab, imaging)**
- ECG should be obtained in most patients.
  - Consider cardiac if there are ischemic changes, bifascicular block, AV block, sinus bradycardia <40 bpm or sinus pause >3 seconds, prolong QTc, preexcitation, and alternating BBB.
- Other testing should be guided by history and physical:
  - Complete blood count, electrolytes, blood urea nitrogen, creatinine, glucose (rarely helpful if asymptomatic or presenting hours later)
  - BNP
– Cardiac enzymes (only if history suggestive of myocardial ischemia)
– D-dimer (for pulmonary embolism [PE] workup)
– Urine pregnancy and urine drug screen
– Initial cardiac or neuroimaging only if indicated
– Lung scan or helical CT scan of chest if concern for PE

Follow-Up Tests & Special Considerations

• Injuries may occur in up to 1/3 of adult patients.

• If history and physical suggest ischemic, valvular, or congenital heart disease (1,3)[B]
  – Exercise stress test (if syncope with exertion) (1,3)[C]
  – Echocardiogram (1,3)[B]

• ECG monitoring, either in hospital or ambulatory (1)[B]
  – Consider when concerned for cardiac cause.
  – Choice of outpatient device (e.g., Holter, loop recorder, implantable monitor) should be determined by frequency of symptoms.

• Electrophysiologic studies (1,3)[B]
  – Consider when concerned for cardiac cause.
  – Positive results seen in 22–82% of patients with preexisting heart disease and/or abnormal ECG

• Head imaging, carotid ultrasound, and electroencephalogram are not recommended in routine evaluation of syncope but may be useful if history and physical is concerning for neurologic issues (1)[C].

• Carotid hypersensitivity evaluation (3)[B]
  – Carotid hypersensitivity should be considered in patients >40 years old or with syncope during head turning, especially while wearing tight collars, and with neck tumors or scars.
  – The technique is not standardized; one side at a time is compressed gently for 20 seconds with constant monitoring of BP and P/ECG. Avoid in patients with history of TIA or stroke.
  – Atropine should be readily available.

• Tilt-table testing (1,3)[B]
  – Provocative test for vasovagal syncope
  – Often, results are not reproducible.
  – High false-positive rate

• Psychiatric evaluation (3)[C]: indicated when syncope is thought to be psychogenic.
  Psychiatric disease and substance abuse may be associated with syncope.

Diagnostic Procedures/Other

External event recorders or implantable loop recorders may be more helpful than short-term ambulatory monitoring; helpful in selective patients with recurrent syncope, with yield of ~55% (1)[B].

Test Interpretation

Depends on etiology and presence of underlying cardiac or neurologic conditions

TREATMENT

• Maintaining good hydration status and normal salt intake are initial therapy. Educate patients of the premonitory signs of syncope (1,4)[B].
Majority of pediatric patients improve with nonpharmacologic measures.

**GENERAL MEASURES**
- NMS: reassurance, education, behavior modification
- Elderly patients without previously recognized heart disease should be admitted if the physician thinks that the cause of syncope is likely cardiac.
- Patients without heart disease, especially young patients (age <60 years), can be worked up safely as outpatients.
- Prescribe antiarrhythmics for documented arrhythmias occurring simultaneously with syncope or symptoms of presyncope. Asymptomatic arrhythmias do not necessarily require treatment.
- The decision to treat patients on basis of arrhythmias or conduction abnormalities provoked or detected during EPS is problematic: Does the arrhythmia or conduction abnormality have anything to do with the patient’s symptoms?
- Most would treat patients with provoked sustained VT with an antiarrhythmic drug that suppressed arrhythmia during study.
- Rationale for such treatment: Recurrent syncope is less frequent in patients with positive EPS who are treated than it is in those who have negative EPS.

**MEDICATION**

First Line
- Geared toward specific underlying cardiac or neurologic abnormalities
- In cases of recurrent NMS and OHT (1)B,(5)
  - Mineralocorticoids (fludrocortisone)
  - α-Adrenergic agonists (midodrine)
  - Norepinephrine precursor (droxidopa)

Second Line
- Selective serotonin reuptake inhibitors (1)C (paroxetine, sertraline, fluoxetine)
- Vagolytics (disopyramide)

**ISSUES FOR REFERRAL**
When cardiac or neurologic etiologies are suspected, obtain appropriate consultation, as indicated.

**ADDITIONAL THERAPIES**
For vasovagal/neurocardiogenic/NMS
- Counterpressure maneuvers and exercise improve vasovagal symptoms and recurrence (1,4) [C].
- Head-up tilt sleeping (3)C
- Abdominal binders and/or support stockings (1,3)C
- Increased fluid and salt intake to maintain intravascular volume in cases of recurrent NMS

**SURGERY/OTHER PROCEDURES**
- ICD placement for patients with cardiac conditions with high risk of sudden death and/or recurrent syncope on medications (e.g., long QT syndrome, Brugada, catecholaminergic polymorphic VT, hypertrophic cardiomyopathy) (1),(3)B
- Many recommend pacemaker implantation in patients with the following:
  - 2nd- (Mobitz type II) and 3rd-degree heart block
- Bifascicular block
- HV intervals >100 ms
- Pacing-induced infranodal block
- Sinus node recovery time ≥3 seconds

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Patients with benign etiologies of syncope with negative emergency department workups are associated with benign outcomes, even with other risk factors (6)[B].
- Overwhelming majority of children who have completely recovered and without red flags for cardiac or neurologic syncope can be followed as outpatients.
- Patients with suspected cardiac or those with significant comorbidities (anemia, associated trauma, or persistent vital sign changes) should be admitted.
- In adults: ROSE (risk stratification of syncope in the emergency department) rule recommends hospital admission if any of the following is present: BNP level ≥300 pg/mL, bradycardia HR ≤50, + fecal occult blood, anemia with hemoglobin ≤9 g/dL, chest pain associated with syncope, ECG showing Q wave (not in lead III), or oxygen saturation ≤94% on room air (7).
- Close monitoring of BP and heart rate during initial presentation
- Discharge criteria
  - Attainment of hemodynamic stability
  - Satisfactory completion of workup for etiology
  - If present, adequate control of arrhythmia or seizure

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Frequent follow-up visits for patients with cardiac causes of syncope, especially if on antiarrhythmics
- Patients with an unknown cause of syncope rarely (5%) are diagnosed during the follow-up.
- Home video recording with smartphone technology is recommended for recurrent episodes.

**DIET**
No specific diet unless the patient has heart disease or NMS (see “Additional Therapies”)

**PATIENT EDUCATION**
- Reassurance that most cardiac causes can be treated, and those with noncardiac causes do well, even if the cause is never discovered
- Physical counterpressure maneuvers can prevent recurrences of vasovagal syncope.
- Carefully consider whether the patient should drive while syncope is being evaluated. Physicians should be aware of pertinent laws in their own states.

**PROGNOSIS**
- Cumulative mortality at 2 years
  - Low: young patients (<60 years of age) with noncardiac or unknown cause of syncope
  - Intermediate: older patients (>60 years of age) with noncardiac or unknown cause of syncope
- High: patients with cardiac cause of syncope
- Independent predictors of poor short-term outcomes (6,7)[B]
  - Abnormal ECG
  - Shortness of breath
  - Systolic BP <90 mm Hg
  - Hematocrit <30%
  - Congestive heart failure

**COMPLICATIONS**
Trauma from falling

**REFERENCES**

**ADDITIONAL READING**

- Aortic Valvular Stenosis; Atrial Septal Defect; Carotid Sinus Hypersensitivity; Patent Ductus Arteriosus; Pulmonary Arterial Hypertension; Pulmonary Embolism; Seizure Disorders; Stokes-Adams Attacks
- Algorithms: Syncope; Transient Ischemic Attack and Transient Neurologic Defects

**CODES**

**ICD10**

R55 Syncope and collapse

**CLINICAL PEARLS**

- Careful history and physical exam are keys to a diagnosis.
- Use the ECG/event-recorder to evaluate for arrhythmias.
- NMS is the most common cause in children and adults.
- True neurologic causes of syncope are rare.
- Injuries due to syncope are common.
SYNCOPE, REFLEX (VASOVAGAL SYNCOPE)
Melinda Y. Kwan, DO, MPH • Norton A. Winer, MD

BASICS
A reversible loss of consciousness and postural tone secondary to systemic hypotension and cerebral hypoperfusion due to vasodilation and/or bradycardia (rarely, tachycardia) with spontaneous recovery and no neurologic sequelae. The term syncope excludes seizures, coma, shock, or other states of altered consciousness.

DESCRIPTION
- Derived from the Greek syncopa, “to cut short”
- Sudden, transient loss of consciousness characterized by unresponsiveness, falling, and spontaneous recovery
- Common cause of syncope in all age groups, especially in patients with no evidence of neurologic or cardiac disease
- Five main types of syncope: vasovagal or neurocardiogenic syncope, situational syncope, orthostatic hypotension, carotid sinus hypersensitivity, and glossopharyngeal trigeminal neuralgia syncope (uncommon) (1)

EPIDEMIOLOGY
- Mortality: cardiac-related syncope 20–30%, and 5% in idiopathic syncope
- Age: any age

Incidence
- Ranges from 7% in children age <18 years and 15% in adults age >70 years
- 36–62% of all syncopal episodes
- 30% recurrence rate

Prevalence
22% in the general population

ETIOLOGY AND PATHOPHYSIOLOGY
Cause: an abnormal interaction of the normal mechanisms for maintaining blood pressure (BP) and upright posture
- In normal individuals, upright posture results in venous pooling and transient decrease in BP.
- Neurally induced syncope may result from a cardioinhibitory response, a vasodepressor response, or a combination of the two.
- Increased cardiovagal tone leads to bradycardia or asystole, and decreased peripheral sympathetic activity leads to venodilation and hypotension (2).
- Vasovagal syncope usually has a precipitating event, often related to fright, pain, panic, exercise, noxious stimuli, or heat exposure (2).
- Carotid sinus syncope is precipitated by position change, turning head, or wearing a tight collar (possible neck tumors or surgical scarring).
- Situational syncope is related to micturition, defecation, postexercise, cough, or swallow (3).
- Glossopharyngeal syncope is related to throat or facial pain.
Genetics
Vasovagal syncope: strong heritable component

RISK FACTORS
- Low-resting BP
- Age: older age
- Prolonged supine position with resulting deconditioning of autonomic control

GENERAL PREVENTION
Avoid precipitating events or situations. Optimize diabetes control, use of elastic stockings, adequate hydration.

COMMONLY ASSOCIATED CONDITIONS
- Cardiopulmonary disorders: congestive heart failure (CHF), myocardial infarction, arrhythmias, hypertrophic obstructive cardiomyopathy, hypertension (HTN), pulmonary embolism (PE)
- Neurologic disorders: autonomic dysfunction, Shy-Drager syndrome, Parkinson disease, multiple system atrophy, transient ischemic attack, vertebrobasilar insufficiency, peripheral neuropathy
- Psychiatric disorders:
  - Generalized anxiety disorder
  - Panic disorder
  - Major depression
  - Alcohol dependence

DIAGNOSIS

HISTORY
- History of syncope during or immediately after exertion is concerning for cardiac syncope.
- Neuromediated syncope is preceded by blurred vision, palpitations, nausea, warmth, diaphoresis, or light-headedness, or there may be history of nausea, warmth, diaphoresis, or fatigue after syncope.
- Vasovagal syncope
  - Three phases: prodrome, loss of consciousness, and postsyncope
  - Precipitating event or stimulus is usually identified, such as panic, fright, pain, or exercise.
  - May be postexertional in athletes (diagnosis of exclusion)
  - Position: can be preceded by prolonged standing but can occur from any position; generally resolves when the patient becomes supine
    - Preceding events: as discussed above
    - Prodrome: as listed above for neurally mediated syncope
  - Duration: generally brief (seconds to minutes)
  - Recovery: may be prolonged with persistent nausea, pallor, and diaphoresis but without neurologic change or confusion
- Carotid sinus syncope is precipitated by position change, after turning head, or wearing a tight collar.
- Situational syncope is related to micturition, defecation, or coughing.
Glossopharyngeal syncope (less common) is related to throat or facial pain.
- Precipitating events or situations may include panic, pain, exercise, micturition, defecation, coughing, or swallowing.
- Pregnant women can have reflex syncope when moving from supine to lateral decubitus or upright positions.

PHYSICAL EXAM
- Vital signs, including orthostatics and bilateral BP
- Cardiac exam: volume status, murmurs, rhythm, carotid bruits
- Neurologic exam: signs of focal deficit
- Assess for occult blood loss.
- Dix-Halpike if benign paroxysmal vertigo is suspected

DIFFERENTIAL DIAGNOSIS
- Seizure
- Arrhythmia
- Hypoglycemia
- Cardiac syncope
- Cerebrovascular syncope
- Orthostatic hypotension
- Drop attacks
- Psychiatric illness

DIAGNOSTIC TESTS & INTERPRETATION
Guided by history and physical, includes basic tests to rule out three primary causes of syncope: hypoglycemia, arrhythmia, and anemia

Initial Tests (lab, imaging)
- Blood glucose (hypoglycemia)
- ECG should be ordered for all patients. Abnormal ECG findings are common in patients with cardiac syncope (arrhythmia).
- CBC (rule out anemia)
- Head CT, MRI/MRA, carotid ultrasound only if history or physical exam suggests a neurologic cause
  - Radiology studies are not indicated for insignificant trauma in the presence of a normal neurologic exam (4).

Follow-Up Tests & Special Considerations
- 24-hour Holter monitoring only if a high probability of cardiac cause and/or abnormal ECG findings is present
- A low hemoglobin without obvious cause of bleed warrants stool guaiac, head CT (rule out subarachnoid hemorrhage), abdominal CT (rule out retroperitoneal bleed).
- Negative imaging prompts workup for alternative causes.
- Stroke, bleed, or carotid stenosis require appropriate disease-oriented management.
- EEG only if history or physical exam suggests seizure
- Implantable loop recorder

Diagnostic Procedures/Other
Head-up tilt table testing:
- Contraindicated in patients with known cardiac or neurovascular disease or in pregnancy
- Indicated for recurrent syncope or single episode accompanied by injury or risk to others (e.g., pilots, surgeons)
- Uses positional changes to reproduce symptoms
- Positive test diagnostic for vasovagal syncope

Carotid sinus massage, only in a monitored setting (i.e., BP and HR monitoring, IV access):
- Contraindicated in patients with carotid disease (careful auscultation prior to massage is essential)
- Pressure at the angle of the jaw for 5 seconds with simultaneous ECG monitoring
- Positive tests (causing syncope or cardiac pause >3 seconds) are diagnostic of carotid sinus syncope.

Psychiatric evaluation: to rule out anxiety, depression, and alcohol abuse

TREATMENT
Therapy is primarily for recurrent syncope. Situational syncope does not warrant specific treatment.

GENERAL MEASURES
Identify and avoid precipitating events or situations

MEDICATION
First Line
- Nonpharmacologic treatment
  - Patient counseling
    - Development of coping skills
    - Increased salt and fluid intake
  - Moderate exercise training
    - Isometric muscle contractions
      - Leg crossing and buttocks clenching
      - Intense gripping of the hands and tensing of the arms
      - These maneuvers increase cardiac output and arterial blood pressure (5).
  - Tilt-table training
    - Progressively prolonged periods of enforced upright posture

Second Line
- α-Agonists mainly used for orthostatic hypotension
  - Midodrine is commonly used. It increases peripheral vascular resistance and venous return.
    - Side effects include HTN, paresthesia, urinary retention, “goose bumps,” hyperactivity, dizziness, tremor, and nervousness.
- SSRIs: Paroxetine and fluoxetine are useful in treating neurocardiogenic/vasovagal syncope.
  - Serotonin affects BP and heart rate (HR) via the central nervous system. Serotonin decreases a sympathetic withdrawal response to rapid increases in serotonin levels.
  - Side effects include weight gain, nausea, anxiety, sexual dysfunction, and insomnia.
- Mineralocorticoids: Fludrocortisone has been found helpful mainly in orthostatic hypotension.
  - Helpful in renal sodium absorption and increasing the vasoconstrictive peripheral vascular
response
- Adverse reactions include fluid retention, HTN, CHF, peripheral edema, and hypokalemia.

- β-Blockers: metoprolol, atenolol, or pindolol mainly for postural orthostatic tachycardia syndrome (POTS)
  - Block peripheral vasodilators and ventricular mechanoreceptor stimulation
  - Stabilization of HR and BP
  - Side effects: hypotension and bradycardia (with worsening of syncope), fatigue, depression, and sexual dysfunction
  - Contraindicated in asthma

ISSUES FOR REFERRAL
Neurology or cardiology, as needed

ADDITIONAL THERAPIES
Use of support/pressure stockings

SURGERY/OTHER PROCEDURES
Pacemaker placement may be of use in patients with frequent neurocardiogenic/vasovagal syncope that is refractory to other therapies (3)[C].
- Prevents prolonged bradycardia or asystole during syncopal episodes
- Long-term effect
- Invasive placement procedure

COMPLEMENTARY & ALTERNATIVE MEDICINE
Treatments for underlying heart disease or precipitating factors (e.g., anxiety); none are proven therapies
- Nutrition and supplements: omega-3 fatty acids, multivitamin, CoQ10, acetyl-L-carnitine, α-lipoic acid, and L-arginine
- Herbs: green tea (Camellia sinensis), bilberry (Vaccinium myrtillus), ginkgo (Ginkgo biloba)
- Homeopathy: carbo vegetabilis, opium, sepia
- Acupuncture: It may precipitate fainting.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Hospital admission or intense evaluation for (6):
- Severe coronary artery disease or structural heart disease (severe CHF, low ejection fraction or previous myocardial infarction, aortic stenosis)
- Arrhythmic syncope:
  - ECG may show bifascicular block, sinus bradycardia <40 without SA block or β-blockers, Brugada syndrome, abnormal QT interval, etc.
- Severe anemia or electrolyte abnormalities
- Family history of sudden death
- Isotonic crystalloids, as needed
- Vital sign monitoring
- Discharge when hemodynamically stable and workup satisfactory

ONGOING CARE
DIET
- Increased salt intake may help if not otherwise contraindicated (2)[C].
- Maintain fluid intake.

PATIENT EDUCATION
- Identify and avoid precipitating events or situations.
- Avoid dehydration, alcohol consumption, warm environments, tight clothing, and long periods of standing motionless.
- Recognize presyncopal symptoms.
- Use behaviors, such as lying down, to avoid syncope.

PROGNOSIS
May be recurrent but not life-threatening

COMPLICATIONS
May result in injury from fall

CODES
ICD10
R55 Syncope and collapse
CLINICAL PEARLS

- A careful history of the events preceding the syncopal episode helps guide evaluation and management.
- Rule out cardiac or neurogenic syncope.
- Prodrome is common with reflex syncope.
- Recovery may be prolonged, with persistent symptoms, but there is no residual neurologic deficit or confusion.
- Patients should avoid precipitating situations or events.
SYNDROME OF INAPPROPRIATE ANTIDIURETIC HORMONE SECRETION (SIADH)

Elise J. Barney, DO

BASICS

DESCRIPTION

- A syndrome of abnormal production of antidiuretic hormone (ADH), despite low serum osmolality, leading to hyponatremia and inappropriately elevated urine osmolality
  - Decreased urinary electrolyte-free water excretion leads to dilutional hyponatremia (total body sodium [Na] levels may be normal or near normal, but the patient’s total body water is increased).
  - Often secondary to medications but may be associated with an underlying disorder, such as neoplasm, pulmonary disorder, or central nervous system (CNS) disease
- Synonym(s): syndrome of inappropriate secretion of ADH; syndrome of inappropriate antidiuresis

EPIDEMIOLOGY

Incidence

- Often found in the hospital setting, where incidence can be as high as 35%
- Predominant age: elderly
- Predominant sex: females > males

ETIOLOGY AND PATHOPHYSIOLOGY

- Drugs:
  - Antidepressants (e.g., SSRIs, tricyclics, monoamine oxidase inhibitors [MAOIs])
  - Antineoplastic drugs (e.g., vincristine, vinblastine, cisplatin, cyclophosphamide)
  - Antipsychotic agents (e.g., risperidone, quetiapine, phenothiazines, haloperidol)
  - Analgesics (e.g., duloxetine, pregabalin, tramadol, NSAIDs)
  - Anticonvulsants (e.g., carbamazepine, oxcarbazepine, valproic acid, phenytoin)
  - Others (e.g., vasopressin, DDAVP, oxytocin, ciprofloxacin, α-interferon, ecstasy)
- Malignancies (ectopic ADH production):
  - Bronchogenic carcinoma
  - Lymphoma
  - Mesothelioma
  - Small cell carcinoma of the lung
  - Pancreatic carcinoma
  - Thymoma
- Pulmonary conditions:
  - Asthma/COPD
  - Atelectasis
  - Cystic fibrosis
  - Positive pressure mechanical ventilation
  - Pneumonia
  - Pulmonary tuberculosis (TB)
Sarcoidosis

**Neurologic causes:**
- Brain tumor
- CNS injury (i.e., subarachnoid hemorrhage, trauma, stroke)
- CNS lupus
- Encephalitis
- Epilepsy
- Guillain-Barré syndrome
- Intracranial surgery
- Meningitis
- Multiple sclerosis

**Other:**
- Acute intermittent porphyria
- Delirium tremens
- HIV infection/AIDS
- Rocky Mountain spotted fever

**Idiopathic**

**Genetics**
- 10% of patients have X-linked mutation of V2R.
- Polymorphisms in TRPV4 gene

**RISK FACTORS**
- Use of predisposing drugs
- Advanced age
- Postoperative status
- Institutionalization

**GENERAL PREVENTION**
- Search for cause, if unknown.
- Reduce/change medications, if drug induced.
- Lifelong restriction of fluid intake

**COMMONLY ASSOCIATED CONDITIONS**
See “Etiology and Pathophysiology.”

**DIAGNOSIS**

**HISTORY**
Symptoms:
- Fatigue
- Anorexia
- Nausea
- Vomiting
- Diarrhea
- Headaches
- Unsteady gait
• Falls
• Myalgias/weakness
• Increased thirst
• Confusion
• Seizures, coma

PHYSICAL EXAM
• Euvolemic state
• Mild hyponatremia (serum Na 125 to 135 mEq/L)
  – Slow cognition and reaction times
  – Hyporeflexia
  – Ataxia
• Moderate to severe hyponatremia (serum Na <125 mEq/L)
  – Altered mental status
  – Lethargy
  – Seizures
  – Psychosis
  – Coma
  – Death

DIFFERENTIAL DIAGNOSIS
• Intravascular volume depletion and thiazide-diuretic induced
• Appropriate ADH secretion secondary to decreased effective arterial blood volume (e.g., congestive heart failure [CHF], nephrotic syndrome, liver cirrhosis)
• Low solute intake hyponatremia
  – “Tea and toast” diet
  – Beer potomania
• Psychogenic polydipsia
  – Intake usually >10 L/day
  – Diuresis occurs when intake is stopped.
• Endocrinopathies
  – Adrenal insufficiency
  – Hypothyroidism
• Translocational hyponatremia: caused by hyperglycemia, mannitol, sucrose, glycine
• Pseudohyponatremia
  – Lab artifact caused by hyperlipidemia, paraproteinemias, administration of IVIG
  – Labs using flame photometry or indirect potentiometry susceptible
• Postoperative complications:
  – Caused by nonosmotic release of ADH, probably mediated by pain afferents
  – ADH stimulated by pain, nausea, vomiting, and hypotension
• Cerebral salt-wasting syndrome (hyponatremia, extracellular fluid depletion, CNS insult)

DIAGNOSTIC TESTS & INTERPRETATION
• Serum Na level: low
• Serum urea level: normal to low
• Serum osmolality: low
• Urine osmolality: high; urine osmolality >100 mOsm/kg H₂O (1)
Urine Na concentration: high; urine Na >30 mEq/L (1)
Fractional excretion of Na >0.5 % (1)
Serum ADH level: high (not clinically useful)
Not usually required for diagnosis but to assist in diagnosis and assess for other causes:
- Serum uric acid
- Serum glucose; creatinine
- Thyroid function
- Morning cortisol

**TREATMENT**

**GENERAL MEASURES**
- Treatment of the underlying cause is essential.
- Requires frequent monitoring (see “Patient Monitoring”)
- Fluid restriction (usually <1,000 mL/day) is the main treatment (2)[B].
- Avoid isotonic saline because this can worsen the hyponatremia.
- Correction of hypokalemia
- Mild asymptomatic hyponatremia (serum Na >125 mEq/L [>125 mmol/L]): Restrict fluid and treat underlying cause.
- Moderate hyponatremia (serum Na 120 to 125 mEq/L):
  - Restrict free water intake.
  - Increase oral solute intake.
  - Calculate urine/plasma electrolyte ratio ([urine Na + K] / [serum Na + serum K]) to determine efficacy of fluid restriction; ineffective if ratio >1 and may need pharmacologic therapy (3)
  - Treat underlying cause/remove offending agent.
- Severe or with neurologic manifestations
  - Hypertonic saline (3% sodium chloride [NaCl] IV bolus)
  - Increase serum Na slowly with hypertonic saline by 4 to 6 mEq/L over 4 to 6 hours (not to exceed 8 mEq/L in a 24-hour period) (1,4)[C].
- Acute (<48 hours duration)
  - Can initially correct rapidly but 24-hour goal is same as in chronic hyponatremia (4)[C]

**MEDICATION**
- If severe or neurologic symptoms: IV 3% NaCl to increase serum Na cautiously (5)[B]:
  - If serum Na <120 mEq/L or severe neurologic symptoms, consider bolus of hypertonic saline to increase serum Na by 4 to 6 mEq/L over the first 4 to 6 hours.
- NaCl oral tablets
- Oral urea is an option but limited due to bitter taste.
- Loop diuretics: furosemide + potassium replacement
- Vasopressin-2 receptor antagonist (the vaptans: tolvaptan, conivaptan) (5)[B]
  - Good efficacy and safety profiles in the treatment of moderate hyponatremia due to SIADH
  - Liberal fluid intake encouraged
  - Must be initiated in hospital setting
  - Cost may limit long-term use.
  - Avoid tolvaptan in patients with liver disease.
Demeclocycline (limited use)

- Blocks ADH at renal tubule; produces nephrogenic diabetes insipidus
- Dosage for long-term management: 300 to 600 mg PO BID
- Onset of action within 1 week; therefore, not best for acute management
- Adverse effects of GI intolerance and nephrotoxicity limit its use.
- Paucity of evidence for efficacy

Contraindications: Avoid fluids in CHF, nephrotic syndrome, or cirrhosis. Avoid tolvaptan in patients with cirrhosis due to possible liver injury.

Precautions: Overly rapid correction (>10 mEq/L/day) can increase risk for osmotic demyelination syndrome (ODS):
- Permanent CNS damage in pons leading to quadriplegia and pseudobulbar palsy
- Increased risk in women, alcoholics, malnutrition, hypoxia, chronic hyponatremia of <110 mEq/L, and hypokalemia

**ALERT**
Increase Na levels slowly, not >8 mEq/L/24 hr, to prevent ODS [1][C].

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Patient Monitoring

- Careful continuous clinical and laboratory monitoring of hyponatremic state during acute phase:
  - Hourly urine output
  - Urine Na, urine potassium, urine osmolality
  - Goal Na increase is <8 mEq/L/24 hr until Na reaches 130 mEq/L [1,4][C].
  - If moderate/severe, check serial serum chemistry every 4 to 8 hours to ensure appropriate rate of correction.
- Chronic management: Treat underlying cause; continue fluid restriction and NaCl tablets as needed; referral to nephrologist

**DIET**
Increase protein/solute intake and decrease water intake.

**PATIENT EDUCATION**
Diet and fluid restrictions

**PROGNOSIS**

- Higher morbidity and mortality in hospitalized patients with hyponatremia [6]
- Higher risk of ICU admission and increased risk of 30-day hospital readmission in hyponatremic patients [6]
- If symptomatic (seizure, coma): high mortality due to cerebral edema if serum Na <120 mEq/L

**COMPLICATIONS**

- Falls and hip fractures
- Cerebral edema (see “Prognosis”)
- Osmotic demyelination with overcorrection (see “Treatment” precautions): central pontine and
extrapontine irreversible myelinolysis (4)

- Chronic hyponatremia
- Chronic hyponatremia is associated with osteoporosis (6)[C].

SEE ALSO

Hyponatremia

CODES

ICD10

E22.2 Syndrome of inappropriate secretion of antidiuretic hormone

CLINICAL PEARLS

- Treatment of the underlying cause is a key. Review all medications for potential culprits.
- Fluid restriction is the mainstay of treatment in SIADH. Fluid restriction fails to correct hyponatremia and Na wasting in salt-losing renal disease.
- Nephrology consultation is recommended in moderate to severe hyponatremia or if hypertonic saline indicated as ODS is a cerebral demyelination syndrome that causes quadriplegia, pseudobulbar palsy, seizures, coma, and death. It is caused by an overly rapid rate of Na correction. Increase Na levels slowly, not >8 mEq/L/24 hr, to prevent ODS.
- Safe correction of hyponatremia is important. Online calculators are available: http://www.medcalc.com/sodium.html.
SYMPHILIS
Melissa Badowski, PharmD, MPH ● Mahesh C. Patel, MD

BASICS

DESCRIPTION
- A chronic, systemic infectious disease caused by Treponema pallidum
- Transmitted sexually by direct contact with an active lesion, vertically (maternal–fetal), and via blood transfusions
- Untreated disease includes four overlapping stages.
  - Primary: single (usually) painless chancre at point of entry; appears in 10 to 90 days; chancre heals without treatment in 3 to 6 weeks
  - Secondary: appears 2 to 8 weeks after primary chancre; nonpruritic rash on palms or soles of feet, mucous membrane lesions, headache, fever, lymphadenopathy, alopecia
  - Latent: seroreactive without evidence of disease
    o Early latent: acquired within the last year
    o Late latent: exposure >12 months prior to diagnosis
  - Tertiary (late): Serology may be negative (fluorescent treponemal antibody absorption [FTA-ABS] test typically positive).
    o Gumma, cardiovascular, and late neurosyphilis; may be fatal
  - Neurosyphilis: any type of CNS involvement; can occur at any stage
    o Psychosis, delirium, dementia
- Syphilis can affect nearly every organ/tissue.

Pediatric Considerations
In noncongenital cases, consider child abuse.

Pregnancy Considerations
- Screen all pregnant patients with venereal disease research laboratory (VDRL) test or rapid plasma reagin (RPR) test early in pregnancy. If high risk, repeat at 28 weeks and at delivery (1,2)[A].
- Use the same nontreponemal test for initial screening and for follow-up (1,2)[A].

EPIDEMIOLOGY

Incidence
- Syphilis rate decreased until 2000 and have since increased (primarily in men who have sex with men [MSM]) (3)
  - All stages: 31 per 100,000
- Congenital: 23/100,000 live births (3)
- Primary and secondary syphilis rates (3)
  - HIV co-infection
    o MSM: 45%
    o Men who have sex with women only (MSW): 9%
    o Women: 4%
  - Male (per 100,000 population)
Prevalence

- Predominant sex: male (88%) > female (12%) (3)
- Greatest increase in MSM (3)

ETIOLOGY AND PATHOPHYSIOLOGY

T. pallidum enters through intact mucous membranes or breaks in skin. The organism quickly enters the lymphatics to cause systemic disease. Highly infectious; exposure to as few as 60 spirochetes is associated with ~50% chance of infection.

RISK FACTORS

MSM, multiple sexual partners, exposure to infected body fluids, IV drug use, transplacental transmission, adult inmates, high-risk sexual behavior, people living with HIV (PLWH)

GENERAL PREVENTION

Education regarding safe sex; condoms reduce but do not eliminate transmission (4)[A].

COMMONLY ASSOCIATED CONDITIONS

HIV infection, hepatitis B, other STIs

DIAGNOSIS

HISTORY

- As a “great imitator,” a high index of suspicion is often required for accurate diagnosis.
- Previous sexual contact with partner with known infection or high-risk sexual behavior
- Genital lesions (chancre—primary syphilis)
- Rash, alopecia, malaise, headache, anorexia, nausea, fatigue (secondary syphilis)
- Mental status changes (tertiary syphilis)

PHYSICAL EXAM

Signs/symptoms depend on stage.
Primary: single (occasionally multiple), usually painless ulcer (chancre) in groin or at other
point of entry; regional adenopathy
Chancres begin as solitary firm, raised painless papules that erode and ulcerate. Spontaneous
healing occurs in 4–8 weeks regardless of treatment
Secondary
– Rash: skin/mucous membranes
  o Rough, red-brown macules, usually on palms and soles
  o May appear with chancre or after it has healed
  o Condylomata lata
  o Alopecia
– Nonspecific symptoms: fever, adenopathy, malaise, headache, hair loss
Tertiary (late) syphilis
– Focal neurologic findings (hearing loss, vision loss; meningeal findings; loss of pain,
temperature; proprioception)
– Gummas (skin, mucous membranes, other organ systems)

DIFFERENTIAL DIAGNOSIS
Primary: chancroid, lymphogranuloma venereum, granuloma inguinale, condylomata
acuminata, herpes simplex, Behçet syndrome, trauma, carcinoma, mycotic infection, lichen
planus, psoriasis, fungal infection
Secondary: pityriasis rosea, drug eruption, psoriasis, lichen planus, viral exanthema, Stevens-
Johnson syndrome
Positive serology, asymptomatic: previously treated syphilis/other spirochetal disease (yaws,
pinta)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Dark-field microscopy demonstrating T. pallidum spirochetes in lesion exudate/tissue biopsy
is gold standard but difficult and not very sensitive (5)[A].
Nontreponemal tests (VDRL/RPR) (3,5)[A]
– Primary screening test: positive within 7 days of exposure
– Nonspecific false-positive results are common; must confirm diagnosis with treponemal
tests
– Positive test should be quantified and titers followed regularly after treatment.
  o Titers usually correlate with disease activity; 4-fold change is clinically significant.
  o Titers decrease with time/treatment; following adequate treatment for primary/secondary
disease, a 4-fold decline is typical in 6 to 12 months.
  o Absence of a 4-fold decline suggests potential treatment failure.
  o ~15% of appropriately treated patients do not have a 4-fold decline in titer 12 months
    after treatment. Management is unclear; repeat HIV testing and/or cerebrospinal fluid
    (CSF) examination and continue to follow titers.
  o With appropriate treatment, titers should become negative (see serofast reaction).
  o Titers of patients treated in latent stages decline more gradually.
– Prozone phenomenon: negative results from high titers of antibody; test with diluted serum.
– Serofast reaction: persistently positive results years after successful treatment; new infection
diagnosed by 4-fold rise in titer
– Conditions that may alter treponemal testing (All stages of syphilis can have a false-
negative RPR result, especially in primary syphilis.)
  - Pregnancy, autoimmune disease, mononucleosis, malaria, leprosy, viral pneumonia, cardiolipin antigens, injection drug use, acute febrile illness, HIV infection; elderly can have false-positive results.
  - TP-PA (T. pallidum particle agglutination) increasingly used for primary testing as high sensitivity overcomes challenges of nontreponemal tests

Treponemal tests (confirmatory test after positive nontreponemal screening test): for example, FTA-ABS, TP-PA (T. pallidum particle agglutination), others (5)[A]:
  - Confirmatory test
  - Usually positive for life after treatment
  - Titers of no benefit
  - 15–25% of patients treated during primary stage revert to serologic nonreactivity after 2 to 3 years.

Lumbar puncture (LP) indicated for (5)[A]:
  - Neurologic, ocular, or auditory manifestations
  - Some advise LP in all secondary and early latent cases—even without neurologic symptoms.
  - PLWH with late latent/latent disease of unknown duration
  - Patients with late latent/latent disease of unknown duration if nonpenicillin therapy planned
  - Treatment failures
  - Evidence of active tertiary syphilis (e.g., aortitis, gumma, iritis)
  - Children to rule out neurosyphilis
  - VDRL, not RPR, used on CSF; may be negative in neurosyphilis; highly specific but insensitive
  - Send CSF for protein, glucose, and cell count.
  - Monitor resolution with cell count at 6 months along with serologies (see “Patient Monitoring”).
  - Negative FTA-ABS or microhemagglutination (MHA)-TP on CSF excludes neurosyphilis (highly sensitive).
  - Positive FTA-ABS or MHA-TP on CSF is not diagnostic because of high false-positive rate.
  - Traumatic tap, tuberculosis (TB), pyogenic/aseptic meningitis can all result in false-positive VDRL.

**TREATMENT**

**GENERAL MEASURES**
- Advise patients to notify partner(s) and to avoid intercourse until treatment is complete (5)[A].
- Test for HIV infection.
- Management of sexual contacts (3,5)[A]
  - Presumptively treat partners exposed within 90 days of diagnosis.
  - Presumptively treat partners exposed >90 days before diagnosis if serologic results are not available immediately and follow-up is uncertain.
  - Presumptively treat those exposed to a patient diagnosed with syphilis of unknown duration who has high treponemal titers (>1:32).
- Long-term sex partners of patients with latent infection should be evaluated clinically (including serologies) and treated accordingly.

**MEDICATION**

**ALERT**

Use bicillin L-A instead of bicillin C-R (combination benzathine–procaine penicillin).

**First Line**

Parenteral penicillin G is the drug of choice. The formulation is determined by the disease stage and clinical presentation.

- **Primary, secondary, and early latent <1 year (5)[A]**
  - Penicillin G benzathine 2.4 million U IM × 1 dose
  - Penicillin-allergic patients: doxycycline 100 mg PO BID for 2 weeks, or ceftriaxone 1 to 2 g IM or IV daily for 10 to 14 days
    - Azithromycin 2 g PO for 1 dose (early syphilis only; should not be used in HIV, MSM, or pregnancy)
    - Resistance and treatment failures have been noted in several U.S. regions.

- **Late latent/late of unknown duration and tertiary without evidence of neurosyphilis (5)[A]**
  - Penicillin G benzathine 2.4 million U IM weekly × 3 doses
  - Penicillin-allergic patients: Attempt desensitization and treatment with penicillin or doxycycline 100 mg PO BID for 28 days; adherence may be an issue.

- **Ocular or neurosyphilis (5)[A]**
  - Aqueous crystalline penicillin G 3 to 4 million U IV q4h as a continuous infusion for 10 to 14 days
  - Alternative: penicillin G procaine 2.4 million U IM daily in conjunction with probenecid 500 mg PO QID for 10 to 14 days (if compliance can be ensured)
  - Penicillin-allergic patients: Attempt desensitization and treat with penicillin; ceftriaxone 2 g/day IM or IV for 10 to 14 days
  - If latent, latent of unknown duration, or tertiary in addition to neurosyphilis, consider treating as late latent after completion of neurosyphilis treatment regimen.

- **Congenital (5)[A]**
  - Aqueous crystalline penicillin G 50,000 U/kg/dose IV q12h for the first 7 days of life and q8h thereafter for a total of 10 days, or penicillin G procaine 50,000 U/kg/dose IM daily for 10 days
  - If negative CSF serologies, normal physical exam, and maternal titer and then 50,000 U/kg penicillin G benzathine IM in single dose
  - If >1 day of drug is missed, restart course.
  - Children (after newborn period): aqueous crystalline penicillin G 50,000 U/kg/dose IV q4–6h for 10 days; late latent, 50,000 U/kg IM as 3 doses at 1-week intervals
  - For contacts without symptoms: Treat as primary disease after serologies are obtained.
  - PLWH and pregnant patients may show poor response to recommended IM doses. Use IV therapy for all treatment failures in these patients.
  - Do not give benzathine or procaine penicillins IV.

- Children (after newborn period) (5)[A]: aqueous crystalline penicillin G 50,000 U/kg/dose IV q4–6h for 10 days; late latent, 50,000 U/kg IM as 3 doses at 1-week intervals

- Pregnancy (5)[A]
– Treatment is same as for nonpregnant patients.
– Some recommend second dose of penicillin G benzathine 2.4 million U IM 1 week after initial dose in 3rd trimester or with primary, secondary, or early latent syphilis.
– Penicillin sensitivity: no proven alternatives to penicillin available for treatment during pregnancy
– Penicillin-allergic patients: Desensitize and treat with penicillin.
– Pregnant PLWH may show poor response to recommended IM doses. Use IV therapy for all treatment failures in these patients.

○ Treat contacts without symptoms as primary disease after obtaining serologies.

○ History of penicillin allergy:
  – Confirmed IgE-mediated reaction: desensitization
  – Questionable history of IgE-mediated hypersensitivity: penicillin skin testing if major and minor penicillin determinants available

○ Precautions (5)[A]
  – PLWH and pregnant patients may show poor response to recommended IM doses. Use IV therapy for all treatment failures in these patients.
  – Do not give benzathine or procaine penicillins IV.

### ONGOING CARE

#### FOLLOW-UP RECOMMENDATIONS

- Clinical and serologic evaluation 6 to 12 months after treatment; if >1 year duration, check at 24 months (5)[A].
- In PLWH, clinical and serologic evaluation at 3, 6, 9, 12, and 24 months after therapy (5)[A].

#### Patient Monitoring

- Use VDRL or RPR test to monitor therapy: 4-fold rise (two dilutions) in titer indicates new infection, whereas failure to decrease 4-fold (two dilutions) in 6 to 12 months may indicate treatment failure (although definitive criteria for cure not established); always use same test (preferably same lab) (5)[A].
- Retreatment for persistent clinical signs or recurrence, 4-fold rise in titers, or failure of initially high titer to decrease 4-fold by 6 to 12 months
- Neurosyphilis: Repeat LP every 6 months to check for normalization of CSF cell count (± CSF-VDRL and protein evaluation) (5)[A].

#### PATIENT EDUCATION

No intimate contacts until 4-fold titer drop

#### PROGNOSIS

- Excellent in all cases except patients with late syphilis complications and with HIV infection
- Syphilis in PLWH
  – Treatment same as for HIV-negative patients
  – More often false-negative treponemal and nontreponemal tests or unusually high titers
  – Response to therapy less predictable
  – Early syphilis: increased risk of neurosyphilis and higher rates of treatment failure
  – Late neurosyphilis: harder to treat; can occur up to 20 years or more after infection
COMPLICATIONS
- Membranous glomerulonephritis
- Paroxysmal cold hemoglobinemia
- Meningitis and tabes dorsalis
- Cardiovascular aneurysms; valvular damage
- Irreversible organ damage
- Jarisch-Herxheimer reaction
  - Fever, chills, headache, myalgias, new rash
  - Common when starting treatment (of primary/secondary disease; less common with tertiary)
  - Owing to treponemal lysis
  - Should not be confused with drug reaction
  - Managed with analgesics and antipyretics

REFERENCES

SEE ALSO
Chlamydia Infection (Sexually Transmitted); Gonococcal Infections

CODES
ICD10
- A53.9 Syphilis, unspecified
- A51.0 Primary genital syphilis
- A53.0 Latent syphilis, unspecified as early or late

CLINICAL PEARLS
- Screen all people living with HIV (PLWH) and patients with high-risk sexual behaviors for syphilis.
- Penicillin is the treatment of choice for syphilis.
- Syphilis rates are rising—particularly among MSM.
**TARSAL TUNNEL SYNDROME**  
Terrence C. Tsui, DO ● J. Herbert Stevenson, MD

**BASICS**

**DESCRIPTION**
Tarsal tunnel syndrome occurs when there is compression neuropathy of the posterior tibial nerve as it passes behind the medial malleolus and under the flexor retinaculum (lacinate ligament) in the medial ankle (the tarsal tunnel).

**EPIDEMIOLOGY**
- Women are slightly more affected than men (56%).
- All postpubescent ages are affected.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Contents within the tarsal tunnel from the anterior medial to the posterior lateral side include the following: the posterior tibial tendon, the flexor digitorum longus tendon, the posterior tibial artery and veins, the posterior tibial nerve, and the flexor hallucis tendon.
- The posterior tibial nerve passes through the tarsal tunnel, which is formed by three osseous structures—sustentaculum tali, medial calcaneus, and medial malleolus—covered by the lacinate ligament.
- Compression of the posterior tibial nerve within the tarsal tunnel results in decreased blood flow, ischemic damage, and resultant symptoms (1).
- Chronic compression can destroy endoneurial microvasculature, leading to edema and (eventually) fibrosis and demyelination (2).
- Increased pressure in the tarsal tunnel is caused by a variety of mechanical and biochemical mechanisms. The specific cause for compression is identifiable in only 60–80% of patients (1).
- Three general categories: trauma, space-occupying lesions, deformity (1)
  - Trauma including displaced fractures, deltoid ligament sprains, or tenosynovitis
  - Varicosities
  - Hindfoot varus or valgus
  - Fibrosis of the perineurium
- Other causes:
  - Osseous prominences
  - Ganglia; lipoma; neurilemmoma
  - Inflammatory synovitis
  - Pigmented villonodular synovitis
  - Tarsal coalition
  - Accessory musculature
- In patients with systemic disease (e.g., diabetes), the “double crush” syndrome refers to the development of a second compression along the same nerve at a site of anatomic narrowing in patients with previous proximal nerve damage (3).

**RISK FACTORS**
- Tarsal tunnel syndrome is associated with certain occupations and activities involving repetitive and prolonged weight-bearing on the foot and ankle (walking, running, dancing).
Other possible risk factors include (4):
- Diabetes
- Systemic inflammatory arthritis
- Connective tissue disorders
- Obesity
- Varicosities
- Heel varus or valgus
- Bifurcation of the posterior tibial nerve into medial and lateral plantar nerves proximal to the tarsal tunnel

**DIAGNOSIS**

Tarsal tunnel syndrome is largely a clinical diagnosis, characterized by pain and paresthesias in a predictable distribution along the medial aspect of the ankle and plantar surface of the foot (1).

**HISTORY**
- History of trauma (which may be trivial) to the foot precipitating pain
- Pain, tightness, burning, tingling, and/or numbness behind medial malleolus radiating to the longitudinal arch and plantar aspect of foot including the heel (1)
- Pain usually worsens during standing or activity.
- Pain radiates proximally up the medial leg (Valleix phenomenon) in 33% of patients with severe compression.
- Some patients have substantial night pain (may be related to venostasis).
- Symptoms improve with rest, wearing loose footwear, and elevation.
- In advanced nerve compression, motor involvement may cause weakness, atrophy, and digital contractures of the intrinsic foot muscles (4).

**ALERT**

Other systemic neuropathies (diabetes, alcoholism, HIV, drug reactions) present with similar symptoms.

**PHYSICAL EXAM**
- Inspect: foot alignment
  - Examine for excessive foot pronation during standing or walking.
  - Examine for hindfoot varus or valgus deformity.
  - Exaggerating heel dorsiflexion, inversion, or eversion may reproduce symptoms by stretching or compressing the posterior tibial nerve.
- Palpate the tarsal tunnel and the course of the tibial nerve for tenderness and swelling.
- Tinel sign: Percussion over the tibial nerve may reproduce paresthesias that radiate distally.
- Valleix sign: Percussion over the tibial nerve may produce paresthesias that radiate proximally.
- Cuff test: Inflating a pneumatic cuff engorges varicosities and reproduces symptoms.
- Compression test: Applying pressure to the tarsal tunnel for 60 seconds may reproduce symptoms.
- Sensory examination
  - The medial calcaneal nerve usually is spared, but numbness and altered sensation may be present in the distribution of the medial or lateral plantar nerves.
  - Vibratory sensation and two-point discrimination are decreased early in the disease process.
Motor examination
- Intrinsic foot muscle weakness (difficult to assess)
- Rarely, weakness of toe plantar flexion may be present.
- Atrophy of the abductor hallucis or abductor digiti minimi may be seen late in the disease process.

DIFFERENTIAL DIAGNOSIS
- Peripheral neuropathies (diabetes, alcoholism, HIV, or drug related)
- Inflammatory arthritis (rheumatoid arthritis)
- Morton neuroma
- Metatarsalgia
- Subtalar joint arthritis
- Tibialis posterior tendinitis/dysfunction
- Plantar fasciitis
- Plantar callosities
- Peripheral vascular disease
- Lumbar radiculopathy
- Proximal injury or compression of the tibial branch of the sciatic nerve

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Routine lab tests help rule out other conditions that may mimic tarsal tunnel syndrome, including diabetic neuropathy, rheumatoid arthritis, thyroid dysfunction, or other systemic illnesses (5).
- Routine weight-bearing radiographs, followed by CT (if necessary) to assess for fracture or structural abnormality
- Consider evaluation of lumbar spine x-ray if double crush (injury to lumbar nerve results in compensatory injury to posterior tibial nerve) is suspected (5).
- MRI: helps assess the tarsal tunnel for soft tissue masses or other sources of nerve compression before surgery (1)
- Ultrasound (US): gaining importance and with several advantages over MRI; can assess for space-occupying lesions (ganglia, varicose veins, lipomas, etc.) and tenosynovitis (1)

Pregnancy Considerations
- Tarsal tunnel syndrome can occur during pregnancy, typically secondary to local compression caused by fluid retention and volume changes (1).
- Care is supportive. Most cases resolve after pregnancy.

Pediatric Considerations
MRI is recommended for evaluating pediatric tarsal tunnel syndrome to exclude neoplastic mass.

Diagnostic Procedures/Other
Electrodiagnostic studies
- Electromyography (EMG) of the intrinsic muscles of the foot can confirm the diagnosis of tarsal tunnel syndrome. A normal EMG does not exclude the diagnosis (false-negative rate is ~10%) (1).
- Nerve conduction studies may reveal slowed conduction of the tibial nerve.
- Evaluate for proximal nerve compression, including a lumbar radiculopathy or a double crush phenomenon.
TREATMENT
- Conservative management is recommended, except for acute onset tarsal tunnel syndrome or in the setting of a known space-occupying lesion (excluding synovitis).
- Tarsal tunnel decompression may improve sensory impairment and restore protective sensation in diabetic peripheral neuropathies if there is nerve entrapment at the tarsal tunnel.

MEDICATION
First Line
- Analgesics and anti-inflammatory medications
- Local corticosteroid injection
- Medications that alter neurogenic pain (tricyclic antidepressants, antiepileptic drugs, nerve blockers)

ADDITIONAL THERAPIES
- Rest/immobilization
- Taping and bracing
- Orthotics or shoe modification
- Night splinting
- Physical therapy to strengthen the intrinsic and extrinsic muscles of the foot and to restore the medial longitudinal arch
- Other modalities (stretching, US, massage, icing)
- Compression stockings to decrease swelling
- Weight loss for obese patients

SURGERY/OTHER PROCEDURES
- Surgery is indicated (1,2).
  - If nonoperative measures fail following a 6-month trial
  - In the setting of acute tarsal tunnel syndrome
  - If there are signs of motor involvement/weakness or muscle atrophy
  - If a space-occupying lesion is identified
- The surgical outcome is dependent on technique and postoperative management. 50–95% of cases have good to excellent outcomes.
- At the time of surgery, assess focal swelling, scarring, or nerve abnormalities and look for a pathologic source of compression.
- Postoperative management includes:
  - Non-weight-bearing splint until incision heals (2 to 3 weeks), followed by progressively increased weight-bearing and range of motion exercises
  - Rest, ice, compression, elevation to limit swelling

ONGOING CARE

PATIENT EDUCATION
- Discuss conservative and surgical options based on individual patient circumstance and preference.
- A decision about surgical intervention should be made with a clear understanding of risks,
benefits, and potential adverse outcomes.

**PROGNOSIS**

Surgery is most helpful for:
- Patients with a positive Tinel sign (3)
- Young patients
- Short period between occurrence of symptoms and surgery <1 year
- Localized space-occupying lesion (1)
- No motor neuron involvement

**COMPLICATIONS**

- The main adverse outcome is an unsuccessful surgical intervention characterized by lack of improvement or recurrence of symptoms (1).
- Causes for a failed tarsal tunnel release include:
  - Incorrect diagnosis
  - Incomplete release
  - Adhesive neuritis (external scar formation)
  - Intraneural damage (systemic disease, direct nerve injury)
  - Failure to treat all sources of nerve compression in a double crush phenomenon
- Electrodiagnostic studies are rarely helpful in determining the cause of a failed tarsal tunnel release.
- Results with surgical revision are poorer than those for the primary surgical release.

SEE ALSO
 Algorithm: Foot Pain

CODES

ICD10
- G57.50 Tarsal tunnel syndrome, unspecified lower limb
- G57.51 Tarsal tunnel syndrome, right lower limb
- G57.52 Tarsal tunnel syndrome, left lower limb

CLINICAL PEARLS
- Tarsal tunnel syndrome typically presents with pain and tingling of the medial ankle and plantar foot.
- Tinel sign is the most sensitive and specific physical examination test for diagnosing tarsal tunnel.
- EMG cannot independently diagnose tarsal tunnel syndrome; it is used to confirm a clinical diagnosis.
- Conservative management is recommended, except for patients with an acute onset tarsal tunnel syndrome or known space-occupying lesion.
TELOGEN EFFLUVIUM
Bonnie A. Buechel, MD, MS • Shawn F. Phillips, MD, MSPT

BASICS
Acute, self-limited diffuse hair loss or hair thinning

DESCRIPTION
Telogen effluvium (TE) is a transient condition in which there is a premature conversion of a significant proportion of anagen (growth phase) hairs into telogen (resting phase) hairs resulting in subsequent increased shedding of these resting hair follicles when the follicles re-enter anagen, and the clinical appearance of moderate to severe hair thinning. Normally, each hair follicle cycles independently through anagen, catagen (end-of-growth transformation), and telogen, with the large majority of hair follicles in anagen at any given time.

Five proposed types of TE:
- Immediate anagen release: a highly common form, lasting 3 to 4 weeks, in which follicles meant to remain in anagen phase enter telogen prematurely due to a signal, including high fever, drug induced, or stress.
- Delayed anagen release: large group of hair follicles that have remained in the anagen phase for an extended period all together enter the telogen phase, resulting in hair loss. Common postpartum.
- Short anagen: a speculative type in which at least 50% of the hair follicles have an idiopathic shortening of the anagen phase. Results in a doubling of the follicles in the telogen phase.
- Immediate telogen release: normal resting club hairs remain within the hair follicle until an unknown signal causes their release, initiating the anagen stage to begin. In this type, the resting club hairs are prematurely released, ending the telogen phase abruptly and causing diffuse shedding.
- Delayed telogen release: the presence of increased visible light, whether it be a seasonal or environmental change, is thought to end a prolonged telogen phase and initiate the anagen phase; results in diffuse shedding of hair follicles

EPIDEMIOLOGY
Incidence
Second most common cause of alopecia

Prevalence
Unknown

ETIOLOGY AND PATHOPHYSIOLOGY
- The hair cycle consists of two predominant phases: the anagen (growth phase) and the telogen (resting phase), which last ~3 years and 3 months, respectively. In a normal scalp, ~10–15% of hairs are in the telogen phase. Due to the presence of some types of external/ internal stress, there may be an increase in the percentage of telogen hairs. As new anagen hairs emerge, these telogen hair follicles are forced out. The preceding event usually occurs 2 to 3 months prior to the appearance of hair loss.
It is hypothesized that substance P plays a key role in the pathogenesis of TE through various mechanisms (1). Studies have been conducted on human hair follicles in vitro and mice hair follicles in vivo, which support this theory.

Role of substance P includes the following (2):
- Upregulation of substance P receptor, NK1, at the gene and protein level, leading to premature catagen development and hair growth inhibition
- Upregulation of nerve growth factor (NGF) and subsequently its hair apoptosis–producing receptor, p75NTR
- Downregulation of hair growth–promoting receptor, TrkA
- Upregulation of major histocompatibility class (MHC) I and β2-microglobulin resulting in loss of hair follicle immune-privilege
- Increase in tumor necrosis factor-α release by mast cells resulting in hair keratinocyte apoptosis

Decreased cortisol levels in chronic stress states may also enhance the effects of substance P.

**RISK FACTORS**
- Infection
- Trauma
- Major surgery
- Thyroid disorder
- Febrile illness
- Malignancy
- Allergic contact dermatitis
- Iron deficiency anemia
- Excess vitamin A
- Protein-calorie restriction
- End-stage liver or renal disease
- Hormonal changes (including pregnancy, delivery, and estrogen-containing medications)
- Chronic stress
- Drug induced (e.g., β-blockers, anticonvulsants, antidepressants, anticoagulants, retinoids, ACE-inhibitors)
- Immunizations

**DIAGNOSIS**

**HISTORY**
- Commonly, an inciting event 2 to 6 months previous to noted hair loss
- Fear of becoming bald
- Patients often present with evidence of hair loss with collections of hair or photographs

**PHYSICAL EXAM**
- Decreased density of hair on the scalp, most commonly involving the crown and temples.
- In rare cases of chronic TE, there is hair loss at the eyebrows and pubic region.
- May have diffuse shedding of hair when fingers are run through the scalp.
- Shed hairs are telogen hairs, which have a small bulb of unpigmented or pigmented keratin on the root end (so-called ‘club’ hairs).
• May affect nail growth, resulting in the appearance of Beau lines, which are transverse grooves on the nails of the hands and feet.

DIFFERENTIAL DIAGNOSIS
• Hypothyroidism
• Hyperthyroidism
• Alopecia areata (diffuse pattern)
• Androgenetic alopecia
• Drug-induced alopecia
• Systemic lupus erythematosus
• Secondary syphilis
• Trichotillomania

DIAGNOSTIC TESTS & INTERPRETATION
Most often, TE is a clinical diagnosis based on typical history and exclusion of other scalp pathology and medical conditions. Blood work may be collected primarily to rule out other possible causes of hair loss. Nutritional deficiencies in iron and zinc have been associated with TE.

Initial Tests (lab, imaging)
If indicated:
• Complete blood count, ferritin
• Thyroid-stimulating hormone
• Creatinine
• Consider iron profile, zinc
• Consider hepatic enzymes
• Consider rapid plasma reagin/venereal disease research laboratory

Diagnostic Procedures/Other
• Hair pull test: unreliable; performed by gently pulling 25 to 30 hairs from various sites on a patient’s scalp. Each pull should elicit <5 normal club hairs; increased quantity may indicate possibility of TE.
• Hair clip test: performed by cutting 25 to 30 hairs from the patient’s scalp and examining them under a microscope. A negative test (not indicative of TE) will demonstrate <10% of hair shafts of small diameter. A positive test will demonstrate >10% of hair shafts of small diameter.
• Trichogram: ~50 hairs are plucked using a hemostat from the patient’s scalp, and the number of telogen and anagen hairs present are counted. In TE, there will be >10% of hairs in the telogen phase.
• Scalp biopsy: rarely needed; it is recommended that several 4-mm punch biopsies be obtained, all horizontally embedded to determine an accurate anagen-to-telogen ratio. Histologically, catagen-to-telogen hairs have numerous apoptotic cells in the outer sheath epithelium. >12–15% of hair follicles in telogen phase is consistent with TE.

TREATMENT
TE is a benign, self-limited process. Identify and correct underlying cause. Patient should be
reassured that hair growth will resume in 3–6 months, with full growth to return in 12–18 months (3). No treatment is required; however, when a nutritional deficiency is identified, there may be some benefit to taking a specific supplement.

**MEDICATION**
- Minoxidil stimulates hair regrowth via arteriolar smooth muscle vasodilation; not effective in TE
- Oral zinc therapy: new medication that may have benefits for patients with TE through various mechanisms all essential to hair growth, including the following (4)[C]:
  - Cofactor for enzymes needed in nucleic acid and protein synthesis and cell division
  - Inhibition of the catagen phase by blocking certain enzymes involved in hair apoptosis
  - Involved in hair growth regulation via hedgehog signaling
- An extract from millet mixed with polar lipids has been found to enhance the cell proliferation in the hair bulb, reduce hair density in the telogen phase, improve scalp dryness, and improve hair brightness.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Combination oral vitamin therapy: A formulation of zinc; biotin; iron; vitamins A, C, E, and B complex; folic acid; magnesium; and amino acids of keratin and collagen was associated with statistically significant improvement compared to a formulation of calcium pantothenate cystine, thiamine nitrate, medicinal yeast, keratin, and aminobenzoic acid in the following measures after 180 days of use: hair loss, hair volume, scalp hair density, hair shine, and hair strength (5)[C].
- An extract from millet mixed with polar lipids has been found to enhance the cell proliferation in the hair bulb, reduce hair density in the telogen phase, improve scalp dryness, and improve hair brightness.

**REFERENCES**

**ADDITIONAL READING**
CLINICAL PEARLS

- TE is a self-limited form of non-scarring alopecia, most often acute.
- TE is due to a premature conversion of a significant proportion of anagen (growth phase) hairs into telogen (resting phase) hairs, resulting in increased shedding of these resting hair follicles and the clinical appearance of moderate to severe hair thinning and loss when growth resumes.
- There are many potential causes of TE, both emotional and physiologic. Often it is hard to determine the etiology, but eliminating the stressor is the key to resolving TE and stimulating new hair growth.
- No treatment is needed. Patient should be reassured that complete hair regrowth will occur in 12 to 18 months.
TEMPOROMANDIBULAR JOINT DISORDER (TMD)
Rita M. Lahlou, MD, MPH ● Benjamin N. Schneider, MD

BASICS

DESCRIPTION
● Syndrome characterized by
  – Pain and tenderness involving the muscles of mastication and surrounding tissues
  – Sound, pain, stiffness, or grating in the temporomandibular joint (TMJ) with movement
  – Limitation of mandibular movement with possible locking or dislocation
  – Recent research suggests that TMD is a complex disorder with multiple causes consistent with a biopsychosocial model of illness (1).
● System(s) affected: musculoskeletal
● Synonym(s): TMJ syndrome; TMJ dysfunction; myofascial pain–dysfunction syndrome; bruxism; orofacial pain

EPIDEMIOLOGY

Incidence
● Annual first-onset incidence is 3.9%.
● Peak incidence in ages 30 to 50 years

Prevalence
● 6–12% in both adults and older children
● Twice as common in female patients
● Up to 1/2 the population may have at least one sign or symptom of TMD, but most are not limited by symptoms, and <1:4 seek medical or dental treatment.

ETIOLOGY AND PATHOPHYSIOLOGY
● Pathophysiology is multifactorial, involving anatomic, behavioral, emotional, and cognitive factors.
● The American Academy of Orofacial Pain categorizes TMD according to three anatomic origins of pain. The change in name from TMJ to TMD emphasizes that many do not suffer from true articular pain.
● Muscle disorders involving the muscles of mastication
  – Occlusomuscular dysfunction (bruxism)
  – Masticatory muscle spasm
  – Myositis
  – Myofibrosis
  – Poorly fitting oral devices (dentures, splints)
  – Contracture
  – Neoplasia
● Articular disorders of the joint
  – Congenital disorders
  – Inflammatory disorders: synovitis, arthritides, capsulitis, ankyloses
  – Avascular necrosis (rare)
  – TMJ disk derangement, osteoarthritis
– Hyper- or hypomobile TMJ
– TMJ trauma: condylar fractures, dislocation
● Cranial bone disorder including the mandible
  – Congenital and developmental disorders
  – Acquired disorders (fracture, neoplasm)
● Current consensus is that TMD is not only a local condition so much as a family of complex
disorders that can lead to chronic pain and often overlap with other chronic pain conditions
that reflect central nervous system sensitization.
● OPPERA study (Orofacial Pain: Prospective Evaluation and Risk Assessment) is assessing the
heterogeneity in these disorders.

Genetics
Research is ongoing in gene polymorphisms associated with TMD and other pain disorders.
These include the catechol O-methyltransferase (COMT) gene, which is thought to be associated
with changes in pain responsiveness.

RISK FACTORS
● Macrotrauma to the face, jaw, and neck, including cervical whiplash injuries and
  hyperextension of jaw
● Rheumatologic and degenerative conditions involving the TMJ
● Psychosocial stress and poor adaptive capabilities
● Repetitive microtrauma from dental malocclusion, including inappropriate dental treatment
● Link with bruxism and jaw/teeth clenching is inconsistent.

GENERAL PREVENTION
● Elimination of tension-causing oral habits
● Reduction in overall muscle tension

COMMONLY ASSOCIATED CONDITIONS
Craniomandibular disorders, somatization disorder, somatoform pain disorder, other chronic pain
syndromes, fibromyalgia, juvenile idiopathic arthritis, tension headache, sleep disturbance,
tobacco use

DIAGNOSIS
● TMD is a clinical diagnosis, and localized pain is the unifying feature.
● Several research classification systems exist. Most share several of the history and physical
  findings listed below.

HISTORY
● Facial and/or TMJ pain
● Locking/catching of jaw; decreased range of motion
● TMJ noises: clicking, grinding, popping
● Headache, earache, neck pain

PHYSICAL EXAM
● Muscle tenderness and restricted pain-free opening are most consistent distinguishing signs.
● Check facial symmetry, muscle hypertrophy, and intraoral exam including tooth wear.
Palpation of muscles of mastication may reproduce pain.
- There may be tenderness over the TMJ.
- Test jaw range of motion (opening, closing, lateral, protrusive) and masticatory muscle strength.
  - Maximal (pain free) jaw opening with interincisal distance <40 mm is suggestive of joint rather than muscle pathology if accompanied by other signs and symptoms (normal 35 to 55 mm).
  - Deviation to the affected side is common.
- Clicking or crepitus of jaw with opening

DIFFERENTIAL DIAGNOSIS
- Condylar fracture/dislocation
- Trigeminal neuralgia
- Dental or periodontal conditions
- Neoplasm of the jaw, orofacial muscles, or salivary glands
- Acute, nondental infection: parotitis, sialadenitis, otitis, mastoiditis
- Jaw claudication: giant cell arteritis
- Migraine or tension-type headache
- Ramsay Hunt syndrome (zoster auricular syndrome)

DIAGNOSTIC TESTS & INTERPRETATION
- There are no labs to rule in TMD.
- Blood work may be useful to rule out other conditions (complete blood count, comprehensive metabolic panel, erythrocyte sedimentation rate, C-reactive protein).

Initial Tests (lab, imaging)
- TMD is a clinical diagnosis based primarily on history and physical exam.
- Often, a poor correlation is found between pain severity and pathologic changes seen in joint or muscle tissues. Consider the following for traumatic, infectious, severe, or treatment-resistant cases, with MRI or CT scan more useful as part of surgical workup:
  - Panoramic dental radiographs are a good first-line screen.
  - CT scan allows fine detail of bony structures, preferred for trauma.
  - Ultrasound (US): Effusion and findings correlate with MRI and subjective pain.
  - MRI: noninvasive study for disc position; more sensitive than US; can help determine need for surgical management

Diagnostic Procedures/Other
- Local anesthetic nerve block can differentiate orofacial pain of articular versus muscular origin.
- Arthroscopy can be diagnostic for cartilage and bony pathology.

Test Interpretation
Positive findings include:
- Condylar head displacement
- Anterior disc displacement
- Posterior capsulitis
- Loosening of disc and capsular attachments
- Chondroid metaplasia of disc leading to disc perforation and degeneration
TREATMENT

Signs and symptoms will abate without any interventions in most patients. 50% report improvement at 1 year and 85% by 3 years. With conservative therapy, symptoms resolve in 75% of cases within 3 months. Only 5–10% will require surgical intervention.

- Patient education and setting expectations are important because there is no “cure” for TMD, yet most patients will improve with limited interventions.
- Psychosocial interventions, including cognitive-behavioral therapy with or without biofeedback (2)[A]
- Behavior modification to eliminate tension-relieving oral habits including heavy chewing of food and nonfood items as well as potential strain from playing musical instruments that stress or strain the jaw (wind, brass, or string) (2)[A]
- Therapeutic exercises, especially if displacement is present, including formal physical therapy
- Occlusal adjustment cannot be recommended for the management or prevention of TMD because there is an absence of evidence from randomized control trials (RCTs) that occlusal adjustment treats or prevents TMD (3)[A],(4).
- Insufficient evidence exists either for or against the use of stabilization splint therapy for the treatment of TMD.
- The American Dental Association recommends a “less is often best” stepwise approach and offers the following stepwise progression for therapy:
  - Eating softer foods
  - Avoiding chewing gum and nail biting
  - Modifying pain with heat or ice
  - Relaxation techniques including meditation and biofeedback
  - Exercises to strengthen jaw muscles
  - Medications
  - Night guards and orthotics

MEDICATION

First Line
- Acetaminophen
- Naproxen: 500 mg BID stronger evidence than for other NSAIDs (5)[B]
- Topical diclofenac
- Gabapentin: Titrate up to 1,800 mg/day divided.
- Ibuprofen, if osteoarthritis is suspected (5)[B]

Second Line
- Cyclobenzaprine 10 mg nightly more effective than placebo for pain reduction (5)[B]
- Tricyclic antidepressants, SSRIs, or SNRIs; however, SSRIs and some SNRIs may also induce bruxism.
- Acupuncture and dry needling can reduce pain (4)[B].
- Opiates should be reserved for perioperative or severe or recalcitrant cases (6)[B].
- DMARDs may benefit inflammatory arthropathies such as rheumatoid or psoriatic arthritis.
- Ineffective medications (6)[B]
  - The following medications when compared with placebo in RCTs were shown to be ineffective in improving pain and should not be used for the treatment of TMD:
Benzodiazepines
- Topical capsaicin
- Celecoxib

ADDITIONAL THERAPIES
Joint and muscle injections
- There is very limited evidence to recommend for or against injections into or around the TMJ. Proposed therapies include steroids, hyaluronic acid, platelet rich plasma, local anesthetics, and botulinum toxin.
- Steroids given >3 times annually may accelerate degenerative changes.
- Injections into inferior space or double spaces have better effect than superior space injections alone.
- A systematic review of studies evaluating botulinum toxin type A (Botox) injections revealed mixed results (4).
- For advanced structural abnormalities, referral for discectomy, arthroplasty, or joint replacement can be considered; however, strong evidence is lacking for lavage or surgical treatments over conservative management (4).

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Glucosamine may be effective if pain is secondary to osteoarthritis of the TMJ (6)[B].
- Multiple electronic diagnostic and treatment modalities are currently marketed to patients; however, the scientific literature does not support the use of electronic diagnostic and treatment devices for TMD at this time.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- Relax jaw by disengaging teeth.
- Avoid wide, uncontrolled opening, such as yawning.
- Stress management and behavior modification counseling may be helpful.
- Be aware of any teeth-clenching or grinding habits.

Patient Monitoring
- Ongoing assessment of clinical response to conservative therapies (NSAIDs, behavior modification, occlusal splints) is necessary.
- Surgical procedure (arthroplasty, joint replacement) to correct disc displacement or replace a damaged disc may be indicated only if the patient has not responded to conservative treatment.

DIET
- Soft diet to reduce chewing

PROGNOSIS
- With conservative therapy, symptoms resolve in 75% of cases within 3 months.
- Patients benefit most from a comprehensive treatment approach including the following (5):
  - Restoration of normal muscle function
  - Pain control
  - Stress management
– Behavior modification

**COMPLICATIONS**
- Secondary degenerative joint disease
- Chronic TMJ dislocation
- Loss of joint range of motion
- Depression and chronic pain syndromes
- Secondary headache disorder

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

Headache, Tension

**CODES**

ICD10
CLINICAL PEARLS

- The condition called TMD actually designates a number of potential underlying joint and muscle conditions involving the jaw. Characteristics of all conditions are pain and functional limitation.
- TMD is a clinical diagnosis; imaging and labs are often of limited utility.
- Cognitive-behavioral therapy reduces pain, depression, and limitation of function.
- Exercises may improve function and pain.
- Evidence is lacking to support occlusion correction or splinting.
- Naproxen, gabapentin, topical methylsalicylate, glucosamine, amitriptyline, acupuncture, and botulinum toxin injections have some evidence of efficacy.
TESTICULAR MALIGNANCIES
Huy T. Tran, MD

BASICS

DESCRIPTION
- Testicular cancer accounts for <1% of all cancers in men; it is the most common solid malignancy in men ages 20 to 34 years (1).
- An estimated 9,560 new cases were diagnosed, and an estimated 410 deaths occurred in the United States in 2019 (2).
- Rates for new cases have been rising 0.8% each year over the last 10 years, but death rates have been stable.
- The median age at diagnosis is 33 years. The median age at death is 42 years (2).
- Treatment produces an overall 5-year survival of 95.3%; for African American patients, this 5-year survival rate is alarmingly lower but has improved from 86% to 90% (2).

EPIDEMIOLOGY

Incidence
The number of new cases of testicular cancer was 5.9 per 100,000 men per year with the number of deaths at 0.3 per 100,000 men per year (2).

Prevalence
In 2016, there were an estimated 263,137 men living with testicular cancer in the United States (2).

ETIOLOGY AND PATHOPHYSIOLOGY
95% of all malignant tumors arising in the testes are germ cell tumors (GCTs), which are subclassified as follows:
- Seminomatous GCTs: most common type overall
- Nonseminomatous GCTs (NSGCTs): These include embryonal cell carcinoma, choriocarcinoma, yolk sac tumor, teratomas, or often multiple cell types; these are more clinically aggressive tumors.

RISK FACTORS
- Cryptorchidism is the most firmly established risk factor: Relative risk of testicular cancer in all patients with cryptorchidism is 3 to 8, with a lower relative risk of 2 to 3 in those undergoing orchiopexy by age 12 years; in patients with unilateral cryptorchidism, the relative risk of testicular cancer in the contralateral normally descended testis is negligible (3).
- Personal history of testicular cancer
- Use of muscle building supplements
- Positive family history for testicular cancer
- Testicular dysgenesis
- Klinefelter syndrome
- Caucasian race
- HIV infections
GENERAL PREVENTION
No evidence that screening for testicular cancer is effective (4)

DIAGNOSIS

HISTORY
- A painless solid testicular mass is pathognomonic for testicular cancer.
- Clinical symptoms of epididymitis or orchitis that do not respond to treatment warrant further evaluation.
- Gynecomastia can be a rare systemic endocrine manifestation of testicular neoplasm.

PHYSICAL EXAM
- Testicular exam: Palpate for size, consistency, and nodules; masses do not transilluminate; a firm, hard, or fixed area should be considered suspicious.
- Lymph node and abdominal exam
- Gynecomastia

DIFFERENTIAL DIAGNOSIS
Epidermoid cyst, epididymitis, hernia, hydrocele, hematoma, lymphoma, orchitis, spermatocele, testicular torsion, varicocele

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Testicular ultrasound (US) is the initial study.
- If an intratesticular mass is identified, measure serum α-Fetoprotein (AFP), lactate dehydrogenase (LDH), and β-human chorionic gonadotropin (β-hCG), and order a chest x-ray (CXR).
- AFP, β-hCG, LDH, creatinine, chemistry profile, complete blood count, liver enzymes, CXR, and testicular US
- Tumor markers AFP, β-hCG, and LDH are used to assist with diagnosis, prognosis, assessing treatment outcome, and monitoring for relapse:
  - AFP
    - Produced by nonseminomatous testicular cancer and is therefore associated with this histologic type
    - Those with a histologically “pure” testicular seminoma and an elevated AFP are assumed to possess an undetected focus of nonseminoma tumor.
  - β-hCG
    - May be associated with both seminomatous or nonseminomatous tumors
    - Hypogonadism and marijuana use may cause benign elevations of β-hCG.

Follow-Up Tests & Special Considerations
- CT scan of the abdomen/pelvis, positron emission tomography (PET) scan, magnetic resonance imaging of the brain, and bone scan are used for staging and metastases evaluation as clinically indicated.
- LDH is less specific than AFP.

Diagnostic Procedures/Other
Radical inguinal orchiectomy is the primary procedure for diagnosis and treatment. Testicular biopsy may be rarely considered if a suspicious intratesticular abnormality is identified on US; however, testicular microcalcification on US without any other abnormality can simply be observed and does not demand a biopsy. For those with unilateral testicular cancer, contralateral testicular biopsy is not routinely performed but should be considered when there is a cryptorchid testis, marked testicular atrophy, or a suspicious US for intratesticular abnormalities.

**Test Interpretation**

Clinical staging (5):

- **Stage 0:** carcinoma in situ
- **Stage IA:** tumor limited to testis and epididymis without vascular/lymphatic invasion; tumor may invade into the tunica albuginea but not the tunica vaginalis; normal serum tumor markers
- **Stage IB:** tumor limited to testis and epididymis with vascular/lymphatic invasion or tumor extending through tunica albuginea with involvement of tunica vaginalis; tumor invades the spermatic cord with or without vascular/lymphatic invasion; tumor invades the scrotum with or without vascular/lymphatic invasion; no lymph node involvement or distant metastasis; normal serum tumor markers
- **Stage IS:** any tumor with elevated serum tumor markers but no nodal involvement or metastasis
- **Stage IIA:** any tumor with lymph node mass/masses <2 cm
- **Stage IIB:** any tumor with lymph node mass/masses 2 to 5 cm
- **Stage IIC:** any tumor with lymph node mass >5 cm
- **Stage IIIA:** any tumor/lymph node presence; with nonregional nodal or pulmonary metastasis; either serum tumor markers normal or with mild elevation
- **Stage IIIB:** any tumor/lymph node presence; no distant metastasis or nonregional nodal involvement or pulmonary metastasis; with moderately elevated serum tumor markers
- **Stage IIIC:** any tumor/lymph node presence; with or without any metastasis; with greatly elevated serum tumor markers

**TREATMENT**

**GENERAL MEASURES**

- **Seminoma:** Specifics are noted in the National Comprehensive Cancer Network guidelines (1):
  - **Stages IA, IB:** Options may include surveillance (preferred) (for low tumor load malignancy, i.e., pT1–pT3), single-agent carboplatin, or radiotherapy.
  - **Stage IS:** Repeat elevated serum tumor marker and abdominal/pelvic CT scan.
  - **Stage IIA:** radiotherapy to include para-aortic and ipsilateral iliac lymph nodes (preferred) or primary chemotherapy
  - **Stage IIB:** primary chemotherapy (preferred) or radiotherapy in select nonbulky cases to include para-aortic and ipsilateral iliac lymph nodes
  - **Stages IIC, III**
    - Good risk (any primary site and no nonpulmonary visceral metastases and normal AFP with any β-hCG or LDH): primary etoposide and cisplatin (EP) or bleomycin, etoposide, and cisplatin (BEP) chemotherapy (1)
    - Intermediate risk (any primary site and nonpulmonary visceral metastases and normal
AFP with any β-hCG or LDH: primary BEP chemotherapy (1)

- Nonseminoma: Tumors with both seminomatous and nonseminomatous histology are managed as nonseminomatous. See “National Comprehensive Cancer Network guidelines” (1):
  - Stage IA: nonseminomatous surveillance protocol (preferred) or nerve-sparing retroperitoneal lymph node dissection (RPLND)
  - Stage IB: nerve-sparing RPLND or primary BEP chemotherapy; for T2 only can enter nonseminomatous surveillance protocol
  - Stage IS: primary chemotherapy followed by response evaluation:
    o Complete response, negative tumor markers: nonseminomatous surveillance protocol
    o Partial response, negative tumor markers: surgical resection of all residual masses
    o Incomplete response: Consider second-line therapy.
  - Stage IIA
    o Negative tumor markers: nerve-sparing RPLND or primary chemotherapy
    o Persistent marker elevation: primary chemotherapy followed by response evaluation
    o Complete response, negative tumor markers: nonseminomatous surveillance protocol or bilateral RPLND +/- nerve-sparing in select cases
    o Partial response, negative tumor markers: surgical resection of all residual masses
    o Incomplete response: Consider second-line therapy.
  - Stage IIB
    o Negative tumor markers: primary chemotherapy or nerve-sparing RPLND in highly selected cases
    o Persistent marker elevation: primary chemotherapy followed by response evaluation
      ■ Complete response, negative tumor markers: nonseminomatous surveillance protocol or bilateral RPLND +/- nerve-sparing in selected cases
      ■ Partial response, negative tumor markers: surgical resection of all residual masses
      ■ Incomplete response: Consider second-line therapy.
  - Stage IIC: primary chemotherapy followed by response evaluation as per stages IIA and IIB
  - Stages IIIA, IIIB, and IIIC: primary chemotherapy depending on risk profile, which is based on tumor, metastases, and postorchiectomy serum tumor markers
- Brain metastases: primary chemotherapy +/- radiotherapy, +/- surgery, as clinically indicated

MEDICATION

First Line
Primary chemotherapy regimens for GCTs:
- EP: etoposide 100 mg/m²/day IV on days 1 to 5, cisplatin 20 mg/m²/day IV on days 1 to 5; repeat every 21 days (1)[A].
- BEP: etoposide 100 mg/m²/day IV on days 1 to 5, cisplatin 20 mg/m²/day IV on days 1 to 5; bleomycin 30 U/dose IV weekly on days 1, 8, and 15 or days 2, 9, and 16; repeat every 21 days (1)[A].
- VIP: etoposide 75 mg/m²/day IV on days 1 to 5; mesna 120 mg/m² slow IV push before ifosfamide on day 1 and then mesna 1,200 mg/m² IV continuous infusion on days 1 to 5; ifosfamide 1,200 mg/m²/day on days 1 to 5; cisplatin 20 mg/m²/day IV on days 1 to 5; repeat every 21 days (1)[A].

Second Line
- These agents are considered in patients who do not respond to first-line therapy or those who
experience a recurrence: carboplatin, cisplatin, etoposide, ifosfamide, mesna, paclitaxel, and vinblastine (1)[A].
- Gemcitabine, oxaliplatin, and paclitaxel are used in palliative chemotherapy regimens (1)[A].

ISSUES FOR REFERRAL
Recurrent cancers should be treated at centers with extensive experience in treating relapsed testicular cancer.

ADDITIONAL THERAPIES
Consider sperm banking before treatment that may compromise fertility; rarely covered by insurance.

SURGERY/OTHER PROCEDURES
- Radical inguinal orchiectomy: primary treatment for testicular cancer for all patients; prosthesis can be inserted at this time.
- RPLND identifies nodal metastases and provides accurate pathologic staging of the retroperitoneum.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Pure seminoma: Specifics are noted in the National Comprehensive Cancer Network guidelines (1)[A]:
  - Stages IA, IB: in general, H&P, optional tumor markers every 3 to 6 months for 1 year, every 6 to 12 months for years 2 to 3, and then annually for years 4 to 5; abdominal/pelvic CT at 3, 6, and 12 months and then every 6 to 12 months for years 2 to 3, every 12 to 24 months for years 4 to 5; CXR, as clinically indicated; less frequent if adjuvant therapy is given
  - Stage IS: Repeat elevated serum tumor marker and assess with abdominal/pelvic CT scan for evaluable disease.
  - Stages IIA, IIB (select): in general, H&P, optional tumor markers every 3 months for year 1, every 6 months for years 2 to 5; abdominal/pelvic CT at 3 and 6 to 12 months, then annually for years 2 to 3, and then as clinically indicated; CXR every 6 months for years 1 to 2
  - Stages IIB (select), IIC, and III: Check all serum tumor markers along with chest, abdominal, and pelvic CT:
    - Residual mass 0 to 3 cm and normal serum tumor markers: H&P, AFP, β-hCG, LDH, CXR every 2 months for year 1, every 3 months for year 2, every 6 months for years 3 to 4, and then annually; abdominal/pelvic CT scan at 3 to 6 months and then as clinically indicated, PET scans as clinically indicated
    - Residual mass >3 cm and normal serum tumor markers: PET scan 6 weeks after chemotherapy:
      - Negative PET scan: abdominal/pelvic CT scans every 6 months for year 1 and then annually for 5 years
      - Positive PET scan: Consider RPLND or second-line chemotherapy or radiotherapy.
  - Any recurrence: Treat according to extent of disease at relapse.
Nonseminoma: Specifics are noted in the National Comprehensive Cancer Network guidelines (1):

- Stages IA and IB on surveillance only: H&P, AFP, β-hCG, LDH every 2 months for year 1, every 3 months for year 2, every 4 to 6 months for year 3, every 6 months for year 4, annually thereafter; CXR and abdominal/pelvic CT depending on stage IA or stage IB
- Follow-up after complete response to chemotherapy and RPLND in general: H&P, AFP, β-hCG, LDH every 2 to 3 months for years 1 to 2, every 6 months for years 3 to 5, annually thereafter; abdominal/pelvic CT every 6 months for year 1, annually for year 2, as clinically indicated thereafter
- Follow-up after RPLND only: H&P, AFP, β-hCG, LDH, CXR every 2 months for year 1, every 3 months for year 2, every 4 months for year 3, every 6 months for year 4, annually thereafter; abdominal/pelvic CT at 3 to 4 months and, as clinically indicated, thereafter; CXR every 2 to 4 months for year 1, 3 to 6 months for year 2, annually thereafter

Patient Monitoring

- No single follow-up plan is appropriate for all patients and should be modified for the individual patient based on sites of disease, biology of disease, and length of time on treatment.
- Monitoring may extend beyond 5 years at the discretion of the physician.

PROGNOSIS

>90% of patients diagnosed are cured, including 70–80% with advanced tumors (1).

COMPLICATIONS

- Surgical: hematoma, hemorrhage, infection, and infertility
- Radiotherapy: radiation enteritis and infertility
- Late complications (6):
  - Cardiovascular toxicity and second malignancies each have a 25-year risk of about 16% in those treated with chemotherapy and/or radiotherapy.
  - Risk for secondary malignancies remains increased for at least 35 years after treatment.
  - Increased incidence of metabolic syndrome occurs and is likely associated with lower testosterone levels.
  - Other late complications associated with chemotherapy, depending on the regimen, include chronic neurotoxicity, ototoxicity, renal function impairment, and pulmonary fibrosis.
- The incidence of late relapse in treated testicular cancer is now estimated to be 2–6%; the time to late relapse ranges from 2 to 32 years, with a median of 6 years (6).

REFERENCES

ADDITIONAL READING

CODES

ICD10
- C62.90 Malig neoplasm of unsp testis, unsp descended or undescended
- C62.00 Malignant neoplasm of unspecified undescended testis
- C62.10 Malignant neoplasm of unspecified descended testis

CLINICAL PEARLS
- Testicular cancer is the most common solid organ tumor in men ages 20 to 34 years.
- Testicular US is initial imaging of choice for testicular pathology.
- Radical inguinal orchiectomy is used for both diagnosis and treatment, with possible radiotherapy or chemotherapy as adjuvant treatment.
- 96% overall survival at 10 years after diagnosis and treatment
# Testicular Torsion

**Jonathan Green, MD, MSCI ● Michael P. Hirsh, MD, FACS, FAAP**

## Basics

### Description
- Twisting of testis and spermatic cord, resulting in acute ischemia and loss of testis if unrecognized:
  - Intravaginal torsion: occurs within tunica vaginalis, only involves testis and spermatic cord
  - Extravaginal torsion: involves twisting of testis, cord, and processus vaginalis as a unit; typically seen in neonates
- System(s) affected: reproductive

### Geriatric Considerations
Rare in this age group

### Pediatric Considerations
Peak incidence at age 14 years \(\text{(1[B])}\)

## Epidemiology

### Incidence
- \(\sim 1/4,000\) males before age 25 years
- Predominant age:
  - Occurs from newborn period to 7th decade
  - 65% of cases occur in 2nd decade, with peak at age 14 years \(\text{(1)}\).
  - Second peak in neonates (in utero torsion usually occurs around week 32 of gestation) \(\text{(1)}\).

## Etiology and Pathophysiology
- Twisting of spermatic cord causes venous obstruction, edema of testis, and arterial occlusion.
- “Bell clapper” deformity is most common anatomic anomaly predisposing to intravaginal torsion:
  - High insertion of the tunica vaginalis on the spermatic cord, resulting in increased testicular mobility within tunica vaginalis
  - Bilateral in \(\sim 80\%\) of patients \(\text{(1[B])}\)
- No clear anatomic defect is associated with extravaginal testicular torsion:
  - In neonates, the tunica vaginalis is not yet well attached to scrotal wall, allowing torsion of entire testis including tunica vaginalis \(\text{(1[B])}\).
- Usually spontaneous and idiopathic \(\text{(1[B])}\)
- 20% of patients have a history of trauma.
- 1/3 have had prior episodic testicular pain.
- Contraction of cremaster muscle or dartos may play a role and is stimulated by trauma, exercise, cold, and sexual stimulation.
- Increased incidence may be due to increasing weight and size of testis during pubertal development.
- Possible alterations in testosterone levels during nocturnal sex response cycle; possible elevated testosterone levels in neonates \(\text{(1[B])}\)
Testis must have inadequate, incomplete, or absent fixation within scrotum (1)[B].
Torsion may occur in either clockwise or counterclockwise direction.

**Genetics**
- Unknown
- Familial testicular torsion, although previously rarely reported, may involve as many as 10% of patients.

**RISK FACTORS**
- May be more common in winter
- Paraplegia
- Previous contralateral testicular torsion

**DIAGNOSIS**

**HISTORY**
- Acute onset of pain, often during period of inactivity
- Onset of pain usually sudden but may start gradually with subsequent increase in severity
- Nausea and vomiting are common:
  - Presence may increase the likelihood of testicular torsion versus other differential diagnoses.
- Prior history of multiple episodes of testicular pain with spontaneous resolution in an episodic crescendo pattern may indicate intermittent testicular torsion.

**PHYSICAL EXAM**
- Scrotum is enlarged, red, edematous, and painful.
- Testicle is swollen and exquisitely tender.
- Testis may be high in scrotum with a transverse lie.
- Absent cremasteric reflex

**DIFFERENTIAL DIAGNOSIS**
- Torsion appendix testis (this may account for 35–67% of acute scrotal pain cases in children)
- Epididymitis (8–18% of acute scrotal pain cases)
- Orchitis
- Incarcerated or strangulated inguinal hernia
- Acute hydrocele
- Traumatic hematoma
- Idiopathic scrotal edema
- Acute varicocele
- Epididymal hypertension (venous congestion of testicle or prostate due to sexual arousal that does not end in orgasm)
- Testis tumor
- Henoch-Schönlein purpura
- Scrotal abscess
- Leukemic infiltrate

**DIAGNOSTIC TESTS & INTERPRETATION**
Doppler US may confirm testicular swelling but is diagnostic by demonstrating lack of blood flow to the testicle; PPV of 89.4% (2,3)[B].

In boys with intermittent, recurrent testicular torsion, both Doppler US and radionuclide scintigraphy findings will be normal (3)[B].

Diagnostic Procedures/Other

- Doppler US flow detection demonstrates absent or reduced blood flow with torsion and increased flow with inflammatory process (reliable only in first 12 hours) (3)[B].
- Radionuclide testicular scintigraphy with technetium-99m pertechnetate demonstrates absent/decreased vascularity in torsion and increased vascularity with inflammatory processes (including torsion of appendix testes) (4)[C].

Test Interpretation

- Venous thrombosis
- Tissue edema and necrosis
- Arterial thrombosis
- Decreased Doppler flow also seen in hydrocele, abscess, hematoma, or scrotal hernia (3)[B]
- Sensitivity of radionuclide testicular scintigraphy is decreased relative to ultrasonography because hyperemia in the torsed testicle can mimic flow (4)[C].

TREATMENT

- Manual reduction: best performed by experienced physician; may be successful, facilitated by lidocaine 1% (plain) injection at level of external ring:
  - Difficult to determine success of manual reduction, especially after giving local anesthesia
  - Even if successful, must always be followed by surgical exploration, urgently but not emergently (5)[C]
- Surgical exploration via scrotal approach with detorsion, evaluation of testicular viability, orchidopexy of viable testicle, orchiectomy of nonviable testicle (2)[B]
- In boys with a history of intermittent episodes of testicular pain, scrotal exploration is warranted with testicular fixation if abnormal testicular attachments are confirmed (2)[B].

GENERAL MEASURES

Early exam is crucial because necrosis of the testicle can occur after 6 to 8 hours (6)[C].

SURGERY/OTHER PROCEDURES

Operative testicular fixation of the torsed testicle after detorsion and confirmation of viability:

- At least 3- or 4-point fixation with nonabsorbable sutures between the tunica albuginea and the tunica vaginalis (2)[B]
- Excision of window of tunica albuginea with suture to dartos fascia (2)[B]
- Any testis that is not clearly viable should be removed (1)[B].
- Testes of questionable viability that are preserved and pexed invariably atrophy (2)[B].
- Bilateral testicular fixation is recommended by many surgeons (2)[B].
- Contralateral testicle frequently has similar abnormal fixation and should be explored (2)[B], (5)[C].
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Postoperative visit at 1 to 2 weeks
- Yearly visits until puberty may be needed to evaluate for atrophy.

DIET
Regular

PATIENT EDUCATION
Possibility of testicular atrophy in salvaged testis with depressed sperm counts. Importantly, fertility rates in patients with one testicle remain excellent.

PROGNOSIS
- Testicular salvage:
  - Salvage is related directly to duration of torsion (85–97% if within 6 hours, 20% after 12 hours <10% if >24 hours) (6)[C].
  - The degree of torsion is related to testicular salvage:
    o The median degree of torsion is <360 in patients who are explored and orchidopexy performed.
- 80–94% may have depressed spermatogenesis related to duration of ischemic injury (possibly related to autoimmune-mediated injury) (6)[C].
- Up to 45% of patients undergoing orchidopexy for testicular torsion will develop atrophy of testicle.

COMPLICATIONS
- Possible testicular atrophy
- Abnormal spermatogenesis
- Infertility:
  - Fertility rates with one testicle remain excellent.
  - Nearly 36% of patients who experience torsion have sperm counts <20 million/mL (4)[C].

REFERENCES
CODES

ICD10
- N44.00 Torsion of testis, unspecified
- N44.01 Extravaginal torsion of spermatic cord
- N44.03 Torsion of appendix testis

CLINICAL PEARLS
- The diagnosis of testicular torsion is usually made by physical exam. Patients with suspected torsion should be taken to the OR without delay. If diagnosis is in question, a testicular Doppler US may be done to evaluate blood flow.
- Although testicular necrosis may be present within 6 to 8 hours of torsion, this is highly variable.
- Infertility can be a problem even if the testicle is viable. Autoimmune antibodies may be produced, and they may affect subsequent fertility.
TESTOSTERONE DEFICIENCY
Stanton C. Honig, MD • Alex M. Hennessey, MD

BASICS

DESCRIPTION
- Testosterone (T) is a critical anabolic hormone.
- It is the principle circulating androgen in males.
- Critical in cardiovascular, reproductive, and metabolic systems
- Testosterone deficiency (TD) is characterized by low levels of T in addition with signs and symptoms.
- No universally accepted threshold of T concentration to distinguish eugonadal from hypogonadal men, but the Federal Drug Administration (FDA) definition is T <300 ng/dL.
- T levels can be affected by disruptions to the hypothalamic–pituitary–testis axis, age, and medical comorbidities.
- T levels correlate with overall health and may be associated with sexual dysfunction.
- Special consideration is needed for men with low T who desire future fertility.
- Synonym(s): hypogonadism; hypoandrogenism; androgen deficiency; low T

EPIDEMIOLOGY

Incidence
- Overall incidence increases with age. T levels decline by 1% per year after age 40.
- 481,000 new cases in United States ages 40 to 69 years

Prevalence
- Estimates of TD vary, typically 20% of men >60 years, 30% >70 years, and 50% >80 years of age.
- Symptomatic TD in United States ages 40 to 69 years is 6–12.3%.
- 2.4 million men in United States ages 40 to 69 years

ETIOLOGY AND PATHOPHYSIOLOGY
- Normal hypothalamic–pituitary–testis axis:
  - Hypothalamus produces GnRH, which stimulates pituitary to produce follicle-stimulating hormone (FSH) and luteinizing hormone (LH).
  - LH stimulates Leydig cells to produce T. Leydig cells are responsible for 90% of the body’s T.
  - T inhibits LH/GnRH through negative feedback. Hence, exogenous testosterone can impair spermatogenesis.
- Primary hypogonadism: Testes produce insufficient amount of T; FSH/LH levels are elevated.
- Secondary hypogonadism: low T from inadequate production of LH
- Congenital syndromes: cryptorchidism, Klinefelter, hypogonadotropic hypogonadism (Kallmann)
- Acquired: cancer, trauma, orchiectomy, steroids
- Infectious: mumps orchitis, HIV, tuberculosis
- Systemic: Cushing, hemochromatosis, autoimmune, severe illness (e.g., renal and liver disease), metabolic syndrome, obesity, obstructive sleep apnea
Medications and drugs: LHRH agonists, corticosteroids, ethanol, marijuana, opioids, SSRIs
Elevated prolactin: prolactinoma, dopamine antagonists (neuroleptics and metoclopramide)

Genetics
- Usually normal
- Klinefelter: XXY karyotype
- Kallmann syndrome: abnormal GnRH secretion due to abnormal hypothalamic development

RISK FACTORS
- Obesity, diabetes, COPD, depression, thyroid disorders, malnutrition, alcohol, stress
- Chronic infections, inflammatory states, narcotic use
- Medications that affect T production or metabolism
- Undescended testicles, varicocele
- Trauma, cancer, testicular radiation, chemotherapy, disorders of the pituitary and/or hypothalamus

GENERAL PREVENTION
General health maintenance and treatment of obesity

COMMONLY ASSOCIATED CONDITIONS
- Infertility, erectile dysfunction, low libido
- Poorer health outcomes
- Osteopenia/osteoporosis
- Diabetes, insulin resistance, metabolic syndrome
- Increased body weight, adiposity
- Depressed mood, poor concentration, irritability
- Chronic narcotic and corticosteroids use

DIAGNOSIS

HISTORY
- Congenital and developmental abnormalities
- Infertility, loss of libido, erectile dysfunction
- Depression, fatigue, difficulty with concentration
- Decreased muscle strength, energy level
- Increase in body fat, development of diabetes
- Bone fractures from relatively minor trauma
- Testicular trauma, infection, radio- or chemotherapy
- Decrease in testicle size or consistency
- Headaches or vision changes
- Medications, narcotic use

PHYSICAL EXAM
- Infancy: ambiguous genitalia
- Puberty
  - Impaired growth of penis, testicles
  - Lack of secondary male characteristics
- Gynecomastia, eunuchoid habitus

**Adulthood**
- Decreased muscular development, visceral fat distribution
- Presence of gynecomastia
- Small and/or soft testicles

**DIFFERENTIAL DIAGNOSIS**
- Delayed puberty
- Obesity, depression, chronic illness, hypothyroidism
- Normal aging
- Prior anabolic steroid abuse

**DIAGNOSTIC TESTS & INTERPRETATION**
- T levels vary widely and are subject to diurnal, seasonal, and age-related variations. There are multiple assays, each with unique characteristics.
- Measurement should be obtained between 6 and 10 AM. Confirmation with a second measurement may be necessary. Free T with total T is generally preferred. Measurements should not be obtained during acute illness. T circulates in blood primarily bound to SHBG or albumin. Only 2–3% of total T is found free. Free and albumin-bound T is considered bioavailable. Laboratory findings must be interpreted in the appropriate clinical setting.
- Lower limit of normal in most labs for total T is 280 to 300 ng/dL. Lower limit of normal for free T is 5 to 9 pg/mL.

**Initial Tests (lab, imaging)**
- Morning T level is initial test. Morning timing is more important for younger men in whom there is more diurnal variation. If initial am T is low, and confirmed on repeat test, further evaluation is appropriate (1).
- Evaluation should include LH and FSH to differentiate between primary versus secondary hypogonadism.
- Consider estradiol and prolactin, especially if LH is low, or breast symptoms and gynecomastia.
- If primary hypogonadism of unknown origin and physical exam reveals abnormalities, consider obtaining karyotype (Klinefelter 1:500 to 1,000 risk).
- If secondary hypogonadism, consider prolactin, iron saturation, pituitary function testing, and/or MRI.
- Imaging is not helpful in the initial diagnosis of TD.
- No evidence to support screening for TD in the general population

**Follow-Up Tests & Special Considerations**
- Prior to initiating therapy:
  - Hemoglobin and hematocrit (to determine risk of polycythemia)
  - Prostate-specific antigen (PSA) in men over 40 years of age (to exclude prostate cancer diagnosis)
  - Estradiol in men with breast symptoms or gynecomastia
- Dual energy x-ray absorptiometry (DEXA) to measure bone mineral density in men with severe TD or fracture from minimal trauma
- Pituitary MRI: if there is elevation of prolactin more than twice the upper limit of normal or LH/FSH below normal range
**TREATMENT**

Testosterone therapy (TT) has been shown to effectively ameliorate many symptoms of TD. TT is recommended for symptomatic men (e.g., low libido and/or erectile dysfunction, low energy level, constitutional symptoms) with low T levels ≤300 ng/dL obtained in the morning; not recommended for older men with low T levels in absence of signs or symptom (2)[C]

- Recent data suggest T replacement can significantly increase hemoglobin levels in men with low T and unexplained anemia.
- Recent data suggest men with low bone mineral density and low T can increase bone density and bone strength with T replacement.
- In older men with low T and age-associated memory impairment, T replacement was not seen as beneficial.

**GENERAL MEASURES**

- Confirm suspicion.
- Prior to TT, obtain hemoglobin/hematocrit, PSA in men >40 years, prolactin, LH/FSH, estradiol.
- Baseline physical exam including digital rectal exam, and International Prostate Symptom Score (IPSS)
- Correction of underlying cause
- Considerations
  - Future fertility? Different treatments are used in men of reproductive age. Impact of exogenous T should be discussed because it relates to fertility.
  - Clinicians should inform patients of the absence of evidence linking TT to the development of prostate cancer (2)[B].
  - Safety of TT in existing prostate cancer is still uncertain and contraindicated in package insert (3)[B].
  - 2018 American Urological Association (AUA) guidelines: Patients with TD and history of prostate cancer should be informed that there is inadequate evidence to quantify the risk–benefit ratio of TT (2)[B].
  - 2018 endocrine guidelines: Patients with organ-confined prostate cancer who have undergone radical prostatectomy and disease free for ≥2 years with undetectable PSA may be considered for TT on an individualized basis.
    - TT should be avoided in men with PSA >4 or PSA >3 and increased risk of prostate cancer (African Americans, men with first-degree relative with prostate cancer)
    - TT should not be used in men with metastatic prostate cancer, breast cancer, hematocrit >54%, untreated obstructive sleep apnea, uncontrolled congestive heart failure (CHF), severe lower urinary tract symptoms with an IPSS >19 (2).
  - TT is not recommended for mood or strength improvement in otherwise healthy men or asymptomatic men with low T (2)[A].
- Carefully weigh risks and benefits in men at elevated cardiovascular disease (CVD) risk.
- 2018 AUA guidelines: Clinicians should inform TD patients that TD is a risk factor for CVD.
  - At this time, cannot state definitively if TT increases risk of cardiovascular events. However, TD is also a risk factor for CVD (2)[A].
  - Patients should be informed that there is no definitive evidence linking TT to a higher incidence of venothrombotic events (2)[A].
Clinicians can consider starting short-term TT as an adjunctive in men with HIV and low T to promote weight maintenance and gains in lean body mass and strength.

Men with TD should be counseled regarding lifestyle modification (2)[C].

**MEDICATION**

**ALERT**
Avoid contact with females or children (see package insert) in patients applying gel preparations.

- Oral therapy with methyltestosterone is not recommended due to association with significant hepatotoxicity.
  - Oral testosterone undecanoate (Jatenzo) was FDA approved in March 2019.
- FDA cautions that TT is approved for men with confirmed low T by blood work with signs and symptoms, not solely due to aging.
- Despite prior data showing no clear association between TT and CVD, several recent papers suggest TT use puts patients at an increased risk for CVD. These papers have been criticized for being flawed due to comparison of unequal groups, short and inaccurate end points, flawed laboratory testing, erroneous exclusion criteria, and atypical statistical analysis. Despite this, an FDA panel concluded that there is a possible increased CVD risk associated with T use.
- TT should NOT be started for a period of 3 to 6 months in patients with acute cardiovascular event.
- TT (FDA-approved)
  - Topical gels/solutions: most common
    - Multiple FDA-approved formulations
    - Most frequently prescribed in United States
    - Mimics normal daily circadian rhythm
    - Good absorption, 15–20% are nonresponders
    - Transfer concern to children and women.
  - Testosterone pellets (Testopel)
    - Minor office procedure
    - Long-acting formulation, 3 to 4 months
    - 1–2% risk of infection or pellet extrusion
  - Transdermal patch (Androderm)
    - Achieves less robust levels
    - Convenient over gels, no risk of transference
    - High incidence of skin irritation
  - Testosterone enanthate (short acting, SC)
    - FDA-approved October 2018
    - SC weekly injection
    - Boxed warning for increased blood pressure
    - Single dose, disposable autoinjector
  - Testosterone cypionate (short acting, IM)
    - Injectable, inexpensive
    - Injections every 1 to 3 weeks
    - Starting dose: 100 mg/week or 200 mg/2 weeks
    - Roller coaster effect: Levels rise and fall.
  - Testosterone undecanoate (long acting, IM)
    - Injectable, expensive, convenient
Small risk of oil embolism, needs observation in office for 30 minutes postinjection
- Given approximately every 8 to 12 weeks
- Buccal application (Striant)
  - Adheres to gum line, irritation in 16.3%
  - Poor compliance, every 12 hours application
- Nasal gel (Natesto)
  - TID dosing, nasal irritation
- Off-label treatment
  - Human chorionic gonadotropin (hCG)
    - Structure similar to LH, mimics its actions
    - 3 times per week starting at 1,500 IU SC
    - Expensive; poor compliance
  - Maintenance of testicular volume and fertility
    - Used in men wanting to preserve fertility
- Clomiphene citrate (Clomid): oral agent
  - Blocks negative feedback of estradiol on pituitary, resulting in increased LH and FSH
  - Starting dose of 25 mg daily 3 to 7 times weekly
  - Used in men wanting to preserve fertility
- Aromatase inhibitors (Arimidex): oral agent
  - Blocks conversion of T to estradiol
  - Does not negatively impact spermatogenesis and testicular volume
  - Used in cases of low T/estradiol ratio
- Combination TT with low-dose hCG may preserve and support fertility in hypogonadal men hoping for future paternity.

ISSUES FOR REFERRAL
- PSA >4 ng/mL or >3 ng/mL in high-risk individuals and/or abnormal prostate exam; worsening symptoms of BPH (IPSS >19) should be referred to urology.
- Worsening CHF, obstructive sleep apnea, polycythemia should be referred to the appropriate providers.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Necessary to monitor effectiveness of therapy as well as for adverse effects: initially 3 to 6 months after treatment initiation and then every 6–12 months
- Adjust dosing to achieve a total T in the middle tertile of the normal reference range.
- Measure hematocrit at baseline, at 3 to 6 months, and then annually. If hematocrit >54% or symptomatic, stop therapy until hematocrit decreases to a safe level. Treatment includes phlebotomy, blood donation, and dose adjustment.
- Clinicians should stop treatment 3 to 6 months after starting in patients who experience normalization of T but fail to achieve symptomatic improvement.
- Bone mineral density after 1 to 2 years of therapy in men with osteoporosis or low trauma fracture
• Prostate exam done regularly every 6 to 12 months
• Refer to urology when increase in PSA >0.7 ng/mL within any 12-month period of T treatment or detection of prostatic abnormality on prostate exam.

DIET
Healthy diet and weight reduction if obese

PATIENT EDUCATION
• TD can be chronic and may need lifelong therapy.
• T replacement comes with many risks, and it is very important to regularly monitor outcomes.
• Women and children must not be allowed to come in contact with TT gel products.

PROGNOSIS
• There is evolving evidence that TT may improve metabolic functions such as glycosylated hemoglobin, blood sugar, total cholesterol, and visceral fat in diabetics, and also unexplained anemia.
• Recent data suggest men with low bone mineral density and low T can increase bone density and bone strength with T replacement.

COMPLICATIONS
Complications of T replacement
• Decreased testicular volume, azoospermia in 40% of patients on TT, infertility
• Fluctuations in mood or libido
• Gynecomastia and growth of breast cancer
• Acne and oily skin
• Erythrocytosis (increased hematocrit)
• Exacerbation of sleep apnea
• Hepatotoxicity with prolonged oral use
• Possible prostate enlargement with or without worsening symptoms of BPH
• Unknown cardiovascular risks

REFERENCES

CODES
ICD10
• E29.1 Testicular hypofunction
• E89.5 Postprocedural testicular hypofunction
CLINICAL PEARLS

- TD is common, and prevalence increases with age.
- TD can have negative adverse impact on many bodily systems.
- Symptomatic men with sexual dysfunction, obesity, unexplained anemia, bone density loss, chronic steroid or narcotic use, and metabolic diseases should be tested for TD.
- Initial test of choice is a morning total and free T; if low, repeat measurements.
- TT in the appropriately selected population can increase lean mass, reduce fat mass, increase bone mineral density, improve libido, improve unexplained anemia, and improve erections. However, it has not been shown to improve cognition or memory impairment in the elderly.
A group of inherited hematologic disorders that affect the synthesis of adult hemoglobin tetramer (HbA) (1,2)[C]

α-Thalassemia is due to a deficient synthesis of α-globin chain, whereas β-thalassemia is due to a deficient synthesis of β-globin chain:
- The synthesis of the unaffected globin chain proceeds normally.
- This unbalanced globin chain production causes unstable hemoglobin tetramers, which leads to hypochromic, microcytic red blood cells (RBCs), and hemolytic anemia.

α-Thalassemia is more common in persons of Mediterranean, African, and Southeast Asian descent, whereas β-thalassemia is more common in patients of African and Southeast Asian descent.

Types
- Thalassemia (minor) trait (α or β): absent or mild anemia with microcytosis and hypochromia
- α-Thalassemia major with hemoglobin Bart usually results in fatal hydrops fetalis (fluid in ≥2 fetal compartments secondary to anemia and fetal heart failure).
- α-Thalassemia intermedia with hemoglobin H (hemoglobin H disease): results in moderate hemolytic anemia and splenomegaly
- β-Thalassemia major: results in severe anemia, growth retardation, hepatosplenomegaly, bone marrow expansion, and bone deformities. Transfusion therapy is necessary to sustain life.
- β-Thalassemia intermedia: milder disease; transfusion therapy may not be needed or may be needed later in life.

Other variants include hemoglobin E/β-thalassemia in Southeast Asians, which often mimics the severity of α-thalassemia major; δ-thalassemia; hemoglobin H Constant Spring

System(s) affected: hematologic/lymphatic/immunologic, cardiac, hepatic

Synonym(s): Mediterranean anemia; hereditary leptocytosis; Cooley anemia

Pediatric Considerations
- β-Thalassemia major causes symptoms during early childhood, usually starting at 6 months of age, and requires periodic transfusions to sustain life.
- Newborn’s cord blood or heel stick should be screened for hemoglobinopathies with hemoglobin electrophoresis or comparably accurate test, although this primarily detects sickle cell disease.

Pregnancy Considerations
- Preconception genetic counseling is advised for couples at risk for having a child with thalassemia and for parents or other relatives of a child with thalassemia (3)[A].
- Once pregnant, a chorionic villus sample at 10 to 11 weeks’ gestation or an amniocentesis at 15 weeks’ gestation can be done to detect point mutations or deletions with polymerase chain
reaction (PCR) technology.

**EPIDEMIOLOGY**

**Incidence**
- Occurs in ~4.4/10,000 live births
- Predominant age: Symptoms start to appear 6 months after birth with β-thalassemia major.
- Predominant sex: male = female

**Prevalence**
- Worldwide, ~200,000 people are alive with β-thalassemia major and <1,000 patients are in the United States.
- In the worldwide population, an estimated 1.5% are β-thalassemia carriers and 5% α-thalassemia carriers (4).

**ETIOLOGY AND PATHOPHYSIOLOGY**
Unknown; it is unclear how the imbalance of β-globulin in α-thalassemia and α-globin in β-thalassemia results in ineffective RBC genesis and hemolysis.

**Genetics**
- Inherited in an autosomal recessive pattern
- α-Thalassemia results from a deletion of ≥1 of the 4 genes, 2 on each chromosome 16, responsible for α-globin synthesis. 1-gene deletion is a silent carrier state, 2-gene deletion is the trait, 3-gene deletion results in hemoglobin H, and 4-gene deletion results in hemoglobin Bart, causing fatal hydrops fetalis.
- Nondeletional forms do occur rarely. Hemoglobin H Constant Spring is the most common nondeletional form.
- β-Thalassemia is caused by any of >200-point mutations and, very rarely, deletions on chromosome 11; 20 alleles account for >80% of the mutations.
- Significantly disparate phenotype with the same genotype occurs because β-globin chain production can range from near-normal to absent.

**RISK FACTORS**
Family history of thalassemia

**GENERAL PREVENTION**
- Prenatal information: genetic counseling regarding partner selection and information on the availability of diagnostic tests during the pregnancy
- Complication prevention
  - For offspring of adult thalassemia patients, an evaluation for thalassemia by 1 year of age
  - Severe forms
    - Avoid exposure to sick contacts.
    - Keep immunizations up to date.
  - Promptly treat bacterial infections. (After splenectomy, patients should maintain a supply of an appropriate antibiotic to take at the onset of symptoms of a bacterial infection.)
  - Dental checkups every 6 months
  - Avoid activities that could increase the risk of bone fractures.

**COMMONLY ASSOCIATED CONDITIONS**
See “Complications.”
DIAGNOSIS
Thalassemia (minor) trait has no signs or symptoms.

HISTORY
- Poor growth
- Excessive fatigue
- Cholelithiasis
- Pathologic fractures
- Shortness of breath

PHYSICAL EXAM
- Pallor
- Splenomegaly
- Jaundice
- Maxillary hyperplasia/frontal bossing due to massive bone marrow expansion
- Dental malocclusion

DIFFERENTIAL DIAGNOSIS
- Iron deficiency anemia
- Other microcytic anemias: lead toxicity, sideroblastic
- Other hemolytic anemias
- Other hemoglobinopathies

DIAGNOSTIC TESTS & INTERPRETATION
Special tests
- Bone marrow aspiration to evaluate for causes of microcytic anemia is rarely needed.
- Multiple indices have been evaluated to discriminate β-thalassemia trait from iron deficiency anemia, yet none is sensitive enough to exclude β-thalassemia.
- Hemoglobin: usual range 10 to 12 g/dL with thalassemia trait and 3 to 8 g/dL with β-thalassemia major before transfusions

Hematocrit
- 28–40% in thalassemia trait
- May fall to <10% in β-thalassemia major

Peripheral blood
- Microcytosis (MCV <70 fl)
- Hypochromia (MCH <20 pg)
- High percentage of target cells
- Reticulocyte count is elevated.

Red cell distribution width (RDW)
- A normal RDW with a microcytic hypochromic anemia is almost always thalassemia trait.
- The RDW can be elevated in ~50% of thalassemia trait patients. This is in contrast to iron deficiency anemia, where the RDW is almost always elevated (90%).

Hemoglobin electrophoresis
- In α-thalassemia trait, no recognizable electrophoretic pattern occurs in adults.
- However, in the neonatal period, 3–10% of trait patients will have hemoglobin H or hemoglobin Bart at birth, which would confirm α-thalassemia.
– If HbA₂ is below normal (<2.5%) with a normal HbF level, the diagnosis is α-thalassemia intermedia (HbH disease).
– In the neonatal period with β-thalassemia trait, the electrophoresis is normal. However, in adults, elevated HbA₂ levels (>4%) may be present but are usually normal (5)[C].
– β-Thalassemia major or intermedia has elevated HbA₂, elevated HbF, and reduced or absent HbA.

DNA analysis
– α-Thalassemia can definitively be diagnosed with genetic testing of hemoglobin A1 and A2 (for deletions and point mutations), but this is not routinely done due to the high cost.
– High-performance liquid chromatography
– Cost-effective primary screening tool for children and adolescents
– Equivocal results should be confirmed with DNA analysis.

Pediatric Considerations
For children, calculate Mentzer index (mean corpuscular volume/RBC count).
– <13: suggests thalassemia
– >13: suggests iron deficiency anemia
– Liver iron concentrations can be assessed with MRI (FerriScan).

**TREATMENT**

– Outpatient for mild cases
– Inpatient for transfusion therapy

**GENERAL MEASURES**

– Mild cases (trait or minor) require no therapy.
– Thalassemia intermedia: No therapy is necessary unless hemoglobin falls to a level that causes symptoms; then, transfusion therapy is needed. Decision is based on patient’s quality of life.
– Iron supplements should not be given unless iron deficiency occurs and is confirmed with low ferritin. Supplements increase the risk of iron overload (1)[C].
– Thalassemia major
  – A regular transfusion schedule to increase posttransfusion hemoglobin to 13.0 to 14.0 g/L and maintain a mean hemoglobin level of at least 9.3 g/dL (1.4 mmol/L) (1)[B]
  – Patients require >8 transfusion events per year. An event may be multiple transfused units.
  – Iron overload (6)[C]
    – Patients receiving transfusion therapy increase total body iron 4 times the normal amount.
    – Therapy is iron chelation. (See “Medication.”)

**MEDICATION**

Thalassemia intermedia and major: folic acid supplements (1 mg/day)

**First Line**

β-Thalassemia major
– Iron chelation with deferoxamine (Desferal)
  – Usually continuous SC or IV infusion
  – Acute toxicity: initial—1,000 mg IV, may be followed by 500 mg every 4 hours for 2 doses; subsequent doses of 500 mg every 4 to 12 hours based on response (max 6,000 mg/day)
– Chronic: 20 to 40 mg/kg over 8 to 12 hours daily
– Usually started by 5 to 8 years of age
– Treatment lasts 3 to 5 years to reach serum ferritin <1,000 ng/mL.

- Deferasirox (Exjade): 20 to 30 mg/kg/day PO acceptable alternative; approved for transfusion and non–transfusion-dependent patients with hepatic iron concentrations ≥5 mg/g of dry weight and serum ferritin >300 μg/L; renal and hepatic monitoring is recommended.

Second Line
Chelation with deferiprone (Ferriprox) 25 mg/kg TID PO initially is an acceptable alternative for patients who have not responded to deferoxamine; may provide more cardioprotection. A drawback is weekly CBC because ~1% of patients develop agranulocytosis.

ISSUES FOR REFERRAL
Thalassemia major usually requires hematology consult.

ADDITIONAL THERAPIES
β-Thalassemia intermedia
- Hydroxyurea may improve hemoglobin 1 to 2 g/dL.
- Psychological support seems appropriate for this chronic disease. However, no conclusions can be made regarding specific psychological therapies.

SURGERY/OTHER PROCEDURES
- Splenectomy
  – May be needed if hypersplenism causes an increase in the transfusion requirements (>180 to 200 mL/kg/year)
  – Defer surgery until patient is at least 4 years of age (due to increased infection risk).
  – Administer pneumococcal polyvalent-23 vaccine 1 month before splenectomy. Children should complete their pneumococcal conjugate vaccine series before surgery.
  – Daily penicillin prophylaxis, 250 mg BID, after splenectomy for 2 years for all patients and for children until age 16 years
- Bone marrow transplantation with HLA-identical related donor stem cells in children before developing hepatitis or iron overload has high likelihood of remission but may impair fertility.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Thalassemia trait requires no restrictions.
- β-Thalassemia major
  – Avoid strenuous activities (e.g., football, soccer).
  – Acceptable activity levels will be determined on an individual basis depending on the severity of the disorder.

Patient Monitoring
- Thalassemia-trait patients require no special follow-up.
- For β-thalassemia major, lifelong monitoring is necessary because the therapy and disease progression have numerous potential complications.
DIET

- Thalassemia trait requires no restrictions.
- β-Thalassemia major
  - Limit intake of iron-rich foods (e.g., red meats such as liver and some cereals).

PATIENT EDUCATION

PROGNOSIS

- Outlook varies depending on type.
- Thalassemia-trait patients live a normal lifespan.
- β-Thalassemia major patients live an average of 17 years and usually die by age 30 years.
- Iron overload causes most of the morbidity and mortality:
  - Cardiac events are the primary cause of death.
  - Myocardial iron deposition is best assessed with MRI T2.
  - Effective iron chelation improves longevity.

COMPLICATIONS

- Chronic hemolysis
- Susceptibility to infections after splenectomy
- Infections from blood transfusion
- Jaundice
- Leg ulcers
- Cholelithiasis
- Osteoporosis and low-trauma fractures
- Impaired growth rate
- Delayed or absent puberty
- Hypogonadism
- Hepatic siderosis
- Splenomegaly
- Cardiac disease from iron overload
- Thromboembolic phenomenon
- Aplastic and megaloblastic crises
- Increased risk of hematologic and abdominal cancer
- Increased risk of dementia

REFERENCES

ADDITIONAL READING

CODES

ICD10
- D56.9 Thalassemia, unspecified
- D56.1 Beta thalassemia
- D56.0 Alpha thalassemia

CLINICAL PEARLS

- Thalassemia (group of inherited hematologic disorders that affect the synthesis of adult hemoglobin tetramer) is a genetic condition; hemoglobin will not improve over time.
- α-Thalassemia is due to a deficient synthesis of the α-globin chain, whereas β-thalassemia is due to a deficient synthesis of the β-globin chain.
- Hemoglobin electrophoresis is needed for genetic counseling but not to make the diagnosis of thalassemia minor when evaluating a patient with mild hypochromic, microcytic anemia and normal serum ferritin.
- Anemia from thalassemia minor is not due to inadequate iron availability or iron storage. Therefore, iron supplements will not improve the anemia and could be harmful due to GI distress and iron overload. If coexisting iron deficiency is proven, then iron therapy is appropriate.
BASICS

DESCRIPTION
- This syndrome consists of a constellation of symptoms that affect the head, neck, shoulders, and upper extremities caused by compression of the neurovascular structures (brachial plexus and subclavian vessels) at the thoracic outlet, specifically in the area superior to the 1st rib and posterior to the clavicle.
- Three forms of thoracic outlet syndrome (TOS) have been described: neurogenic, vascular (with venous and arterial symptoms), and nonspecific (includes traumatic and secondary to certain provocative movements).
- Synonym(s): scalenus anticus syndrome; cervical rib syndrome; costoclavicular syndrome

Pregnancy Considerations
Generalized tissue fluid accumulations and postural changes may aggravate symptoms.

EPIDEMIOLOGY

Incidence
- Predominant age
  - Neurogenic type (95%): 20 to 60 years
  - Venous type (4%): 20 to 35 years
  - Arterial type (1%; atherosclerosis): young adult or >50 years
- Predominant sex
  - Neurogenic type: female > male (3.5:1)
  - Venous type: male > female
  - Arterial type: male = female
- No objective confirmatory tests available to measure true incidence
- Estimated 3 to 8/1,000 cases for neurogenic type
- Incidence of other TOS types is unclear.

ETIOLOGY AND PATHOPHYSIOLOGY
The interscalene triangle area is reduced in TOS and may become smaller during certain shoulder and arm movements. Fibrotic bands, cervical ribs, and muscle variations may further narrow the triangle. Trauma or provocative movements affecting the lower brachial plexus have strong implications in TOS pathogenesis.
- Three known causes of TOS: anatomic, traumatic/repetitive movement activities, and neurovascular entrapment
  - Anatomic: Variations in the anatomy of the neck scalene muscles may be responsible for presentations of the neurologic type of TOS and may involve the superior border of the 1st rib. Cervical ribs also have been implicated as a cause of neurologic TOS, with subsequent neuronal fibrosing and degeneration associated with arterial hyalinization in the lower trunk of the brachial plexus. Fibrous bands to cervical ribs are often congenital.
  - Trauma or repetitive movement activities: Motor vehicle accidents with hyperextension injury and resulting fibrosis, including fibrous bands to the clavicle; musicians who...
maintain prolonged positions of shoulder abduction or extension may be at increased risk.

RISK FACTORS
- Trauma, especially to the shoulder girdle
- Presence of a cervical rib
- Posttraumatic, exostosis of clavicle or 1st rib, postural abnormalities (e.g., drooping of shoulders, scoliosis), body building with increased muscular bulk in thoracic outlet area, rapid weight loss with vigorous physical exertion and/or exercise, pendulous breasts
- Occupational exposure: computer users; musicians; repetitive work involving shoulders, arms, hands
- Young, thin females with long necks and drooping shoulders

GENERAL PREVENTION
Consider workplace evaluation for proper occupational ergonomics.

COMMONLY ASSOCIATED CONDITIONS
- Paget–Schroetter syndrome: thrombosis of subclavian vein
- Gilliatt-Sumner hand: neurogenic atrophy of abductor pollicis brevis

DIAGNOSIS
HISTORY
- Neurologic type, upper plexus (C4–C7)
  - Pain and paresthesias in head, neck, mandible, face, temporal area, upper back/chest, outer arm, and hand in a radial nerve distribution
  - Occipital and orbital headache
- Neurologic type, lower plexus (C8–T1)
  - Pain and paresthesias in axilla, inner arm, and hand in an ulnar-nerve distribution, often nocturnal
  - Hypothenar and interosseous muscle atrophy
- Venous type: arm claudication, cyanosis, swelling, distended arm veins
- Arterial type: digital vasospasm, thrombosis/embolism, aneurysm, gangrene

PHYSICAL EXAM
- Positive Adson maneuver (head rotation to the affected side with cervical extension and then deep inhalation); test is positive if paresthesia occurs or if radial pulse is not palpable during maneuver.
- Tenderness to percussion or palpation of supraclavicular area
- Worsening of symptoms with elevation of arm, overhead extension of arms, or with arms extended forward (e.g., driving a car, typing, carrying objects); prompt disappearance of symptoms with arm returning to neutral position
- Morley test
  - Brachial plexus compression test in the supraclavicular area from the scalene triangle
  - Positive with reproduction of an aching sensation and typical localized paresthesia
- Hyperabduction test: diminishment of radial pulse with elevation of arm above the head
Military maneuver (i.e., costoclavicular bracing): When patient elevates chin and pushes shoulders posteriorly in an extreme “at-attention” position, symptoms are provoked.

1-minute Roos test
- A thoracic outlet shoulder girdle stress test
- Shoulders and arms are braced in a 90-degree abducted and externally rotated position; patient is required to clench and relax fists repetitively for 1 minute.
- A positive test reproduces the symptom.

DIFFERENTIAL DIAGNOSIS
- Cervical disk or carpal tunnel syndrome
- Orthopedic shoulder problems (shoulder strain, rotator cuff injury, tendinitis)
- Cervical spondylitis
- Ulnar nerve compression at elbow and hand
- Multiple sclerosis
- Spinal cord tumor/disease
- Angina pectoris
- Migraine
- Complex regional pain syndromes
- C3–C5 and C8 radiculopathies

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Complete blood count, erythrocyte sedimentation rate, and C-reactive protein (CRP) determination may rule out underlying inflammatory conditions.
- Radiograph (chest, C-spine, shoulders) may reveal elongated C7 transverse process or a cervical rib, Pancoast tumor, or healed clavicle fracture.
- Nerve conduction studies and electromyography (EMG)
- CT scan or MRI, although MRI is the method of choice when searching for nerve compression
- Improved high-resolution MRN and tractography are valuable tools for identifying the source of nerve compression in patients with neurogenic TOS and can augment current diagnostic modalities for this syndrome (1)[B].
- Contrast-enhanced 3D MRA using provocative arm positioning allows excellent imaging of the arteries and veins on both sides and thus provides a noninvasive imaging alternative to digital subtraction angiography in patients with suspected vascular TOS (2)[B].
- Doppler and duplex ultrasound (US) if vascular obstruction is suspected
- Arteriogram and venogram have limited roles; useful when symptoms suggestive of arterial insufficiency or ischemia, or in planning surgical intervention (3)[C]

Diagnostic Procedures/Other
No indicated procedures; anesthetic anterior scalene block may relieve pressure by scalene muscles on the brachial plexus, making this type of block diagnostic and potentially therapeutic, but it poses the risk of procedural damage to the brachial plexus.

TREATMENT

GENERAL MEASURES
Conservative management usually involves approaches to reduce and redistribute pressure and traction through the use of physiotherapy or prosthesis.

- Physical therapy is first-line treatment (4)[B].
- Interscalene injections of botulinum toxin have been shown to decrease symptoms of TOS (5) [C]. A single, CT-guided Botox injection into the anterior scalene muscle may offer an effective, minimally invasive treatment for neurogenic TOS (NTOS) (6)[A].
- Physical therapy will develop strength in pectoral girdle muscles and achieve normal posture.
- Severe cases may use taping, adhesive elastic bandages, moist heat, a TENS unit, or US but should not substitute active exercise and correction of posture and muscle imbalance (4)[B].

MEDICATION

No firm evidence exists for any specific approach to the four types of TOS.

- Anti-inflammatory (ibuprofen)
  - Adult dose: 400 to 800 mg PO q8h; not to exceed 3,200 mg/day
  - Pediatric dose
    - <12 years: 10 mg/kg/dose every 6 to 8 hours
    - >12 years: as in adults
  - Contraindications: documented hypersensitivity, active PUD, renal or hepatic impairment, recent use of anticoagulants, hemorrhagic conditions
- Neuropathic pain: Tricyclic antidepressants, carbamazepine, gabapentin, phenytoin, pregabalin; muscle relaxants such as baclofen, metaxalone, or tizanidine may be helpful.
- Severe pain: Consider opiates for brachial plexus nerve block, steroid injections.

ISSUES FOR REFERRAL

- Neurologic, anesthesiologic, orthopedic, vascular surgery referral(s) may be indicated depending on the type of pathologic condition.
- Physical and rehabilitation physicians

SURGERY/OTHER PROCEDURES

- Operative if vascular involvement is present and/or loss of function or lifestyle occurs secondary to severity of symptoms and if conservative therapy fails after 2 to 3 months
- Resection of 1st rib or cervical ribs via transaxillary (preferred with good to excellent outcome in 80% of patients), supraclavicular (good to excellent outcome in 80% of patients), posterior approaches (reserved for complicated TOS due to necessity of large muscle incision). Excellent results were seen in patients who underwent 1st rib resection in all three forms of TOS (7)[A].
- Transaxillary approach provides good exposure and cosmetics in patients with TOS. It should be considered as the gold standard in the management of TOS (8)[B].
- Supraclavicular scalenectomy (9)[C]
- Isolated pectoral minor tenotomy (PMT) is a low-risk outpatient procedure that is effective for the treatment of selected patients with disabling NTOS, with early outcomes similar to supraclavicular decompression = PMT (10)[A].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Conservative, outpatient, nonpharmacologic treatment is reasonable first-line therapy except in cases of thromboembolic phenomena and acute ischemia, symptoms of chronic vascular occlusion, stenosis, arterial dilatation, or progressive neurologic deficit (6)[B].
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Correct improper posture, practice proper posture, exercises to strengthen shoulder elevator and neck extensor muscles, stretching exercises for scalene muscles, support bra for women with pendulous breasts, breast reduction surgery in selected cases; sleep with arms below chest level, avoid/reduce prolonged hyperabduction.

Patient Monitoring
Office follow-up visits every 3 to 4 weeks

PATIENT EDUCATION
Physical therapy, postural exercises, ergonomic workstation

PROGNOSIS
Durable long-term functional outcomes can be achieved predicated on a highly selective approach to the surgical management of patients with TOS. A majority of operated patients will not require adjunctive procedures or chronic narcotic use (11)[C].

COMPLICATIONS
- Postoperative shoulder, arm, hand pain, and paresthesias in 10%
- Patients who will have symptomatic recurrences at 1 month to 7 years postoperatively (usually within 3 months): 1.5–2%
- Patients who will have brachial plexus injury, probably due to intraoperative traction: 0.5–1%
- Reoperation is indicated for symptomatic recurrence with long posterior remnant of 1st rib (posterior approach) or with disrupted fibrous adhesions (transaxillary approach).
- Venous obstruction or arterial emboli; usually responds to thrombolytics

REFERENCES

ADDITIONAL READING

CODES
ICD10
G54.0 Brachial plexus disorders

CLINICAL PEARLS
- This syndrome is caused by compression of the neurovascular structures (brachial plexus and subclavian vessels) at the thoracic outlet, specifically in the area superior to the 1st rib and posterior to the clavicle.
- Conservative management involves approaches to reduce and redistribute pressure and traction through the use of physiotherapy or prosthesis.
- Physical therapy is first-line treatment.
- Avoid opiate dependence.
- Consider pain clinic referral if there are nonsurgical causes.
BASICS

DESCRIPTION
- An inherited or acquired disorder of the coagulation system predisposing an individual to thromboembolism (the formation of a venous or, less commonly, an arterial blood clot).
- Venous thrombosis typically manifests as deep venous thrombosis (DVT) of the lower extremity in the legs or pelvis and pulmonary embolism (PE).
- System(s) affected: cardiovascular, nervous, pulmonary, reproductive, hematologic
- Synonym(s): hypercoagulation syndrome; prothrombotic state

EPIDEMIOLOGY
- An inherited thrombophilic defect or risk can be detected in up to 50% of patients with venous thromboembolism (VTE).
- Factor V Leiden is the most common inherited thrombophilia (1/2 of all currently characterizable inherited thrombophilia cases involve the factor V Leiden mutation), and it is present in its heterozygous form in up to ~20% of patients with a first VTE.
- Heterozygous prothrombin G20210A mutation, the second most common inherited thrombophilia, is present in up to ~8% of patients with VTE.
- Overall VTE incidence is higher in African-American populations and lower in Asian, Asian-American, and Native-American populations (1).
- VTE rates are higher in women during childbearing years (16 to 44 years), then higher in men when >45 years of age (1).

Incidence
First-time thromboembolism
- ~100/100,000/year among the general population
- <1/100,000/year in those age <15 years
- ~1,000/100,000/year in those age ≥85 years

Prevalence
- 40–80% of lower extremity orthopedic procedures can result in DVT if prophylaxis is not used.
- VTE accounts for ~1.2 to 4.7 deaths per 100,000 pregnancies.

ETIOLOGY AND PATHOPHYSIOLOGY
- Virchow triad as a cause of VTE includes blood stasis, vascular endothelial injury, and abnormalities in circulating blood constituents (i.e., hypercoagulability).
- An imbalance between the hemostatic and fibrinolytic pathways leads to thrombus formation.
- VTE is considered to be the result of genetic tendencies with other acquired risks.
- Upper extremity DVT: >60% are associated with venous catheters. Malignancy is an additional significant risk (2).

Genetics
The most common genetic thrombophilias (factor V Leiden, prothrombin G20210A, proteins C and S defects, and antithrombin III deficiency) are inherited in an autosomal dominant pattern.

Homozygous mutations generally have a higher risk of VTE.

Factor V Leiden/activated protein C (aPC) resistance is the most common inherited thrombophilia.

- 2–5% prevalence among Caucasians; rare in African Americans or Asians
- aPC does not cleave factor Va, so thrombin formation continues.
- Other acquired risks are synergistic (3).

Prothrombin gene mutation G20210A: prevalence 6% among Caucasians. Heterozygous carriers have increased risk of thrombosis.

Hyperhomocysteinemia: 5–6% among the general population; increases risk of coronary artery disease/myocardial infarction, cerebrovascular accident, and DVT/PE; acquired in those with folate, vitamin B\textsubscript{12}, and vitamin B\textsubscript{6} deficiencies

Antithrombin deficiency: <0.2% among the general population; produced in the liver; acquired deficiency in disseminated intravascular coagulation (DIC), sepsis, liver disease, nephrotic syndrome; relative risk (RR) of 8.1 for thrombosis

Protein C and S deficiencies: 0.5% and 1% incidences, respectively, among the general population. Homozygotes and heterozygotes are hypercoagulable. Vitamin K–dependent, produced in the liver. Protein C inactivates Va and VIIIa. Protein C may become an acquired deficiency in liver disease, sepsis, DIC, acute respiratory distress syndrome, and after surgery. RR of 7.3 for thrombosis. Protein S is a cofactor for protein C, and it may become an acquired deficiency with oral contraceptive pill (OCP) use, pregnancy, liver disease, sepsis, DIC, HIV, and nephrosis; RR of 8.5 for thrombosis

RISK FACTORS

Acquired risk factors
- Immobilization or prolonged travel
- Trauma
- Surgery, especially orthopedic
- Malignancies (especially pancreatic, ovarian, brain, and lymphoma)
- Pregnancy
- Acute medical illness
- Exogenous female hormones/oral contraceptives
- Obesity
- Nephrotic syndrome
- Antiphospholipid syndrome (APS) and lupus anticoagulant
- Myeloproliferative disorders (polycythemia vera, essential thrombocythemia)
- Hyperviscosity syndromes (sickle cell, paraproteinemias)
- Hyperhomocysteinemia secondary to vitamin deficiencies (B\textsubscript{6}, B\textsubscript{12}, folic acid)
- Tamoxifen, thalidomide, lenalidomide, bevacizumab, L-asparaginase, erythropoiesis-stimulating agents
- Previous thromboembolism

Established genetic factors
- Factor V Leiden
- Prothrombin G20210A mutation
– Protein C deficiency
– Protein S deficiency
– Antithrombin III deficiency

● Rare genetic factors
  – Dysfibrinogenemia
  – Hyperhomocysteinemia (methylene tetrahydrofolate reductase mutation)

● Indeterminate factors
  – Elevated factor VIII

● Age: >60 years
● Sex: male
● Race: See “Epidemiology.”

GENERAL PREVENTION

● Consider medication prophylaxis in any hospitalized patient with VTE risk factors; hospitalized patients should be encouraged to ambulate as soon as possible (4)[A].

● Consider mechanical prophylaxis in patients at increased risk for VTE in whom anticoagulation may be contraindicated (4)[A].

● Consider prophylaxis with low-molecular-weight heparin (LMWH) plus aspirin in pregnant patients with APS or other thrombophilia.

● Consider prophylaxis using LMWH in patients with solid tumors who have additional risk factors for VTE.

● Prophylaxis with unfractionated heparin (UFH) or LMWH should be considered in patients with genetic or acquired risks of thrombosis and an anticipated additional risk, such as the immobilization associated with surgery.

● Use caution with procoagulant medicines (e.g., OCPs) in asymptomatic individuals who have a known hereditary predisposition.

COMMONLY ASSOCIATED CONDITIONS

Advanced age, cancer, pregnancy, obesity, prior history of thrombosis, surgery, immobilization

DIAGNOSIS

HISTORY

Consider prothrombotic assessment for the following:

● Thrombosis at an unusual anatomic site or recurrent thromboses

● Family history suggesting multiple individuals affected with VTE

● Recurrent pregnancy loss

PHYSICAL EXAM

● DVT: swelling, pain, warmth, and redness, usually of one extremity

● PE: dyspnea, chest pain, hemoptysis, hypoxia, tachycardia

● Postthrombotic syndrome: pain, swelling, pigmentation, and/or ulceration

DIAGNOSTIC TESTS & INTERPRETATION

Testing for thrombophilias is not recommended unless it will affect management (2,5)[B].

Testing should be delayed until after the initial 3 months of anticoagulation (2,5)[B].
**Initial Tests (lab, imaging)**
- Complete blood count
- aPC profile: $\leq 2.0$ implies factor V Leiden mutation; 95–100% are factor V Leiden positive; false-positive finding in pregnancy or with use of OCPs, confirm with factor V Leiden mutation testing or consider factor V Leiden mutation testing up front.
  - aPC resistance may be unreliable while taking LMWH or UFH.
- Prothrombin G20210A genetic assay
- ATIII functional assay
  - Will be low with acute thrombosis and on heparin therapy; may be falsely high on dabigatran, apixaban, edoxaban, and rivaroxaban
- Protein C functional assay
  - May be low with acute thrombosis; will be lower on warfarin, dabigatran, apixaban, edoxaban, and rivaroxaban
- Protein S antigen and functional assay and free S
  - May be low with acute thrombosis; will be lower on warfarin, dabigatran, apixaban, edoxaban, and rivaroxaban
- Antiphospholipid antibodies: phospholipid-dependent tests and anticardiolipin antibodies, lupus anticoagulant
  - May be unreliable on heparin
- Consider evaluation for subclinical malignancy in an unprovoked thrombosis in those $>40$ years of age or at greater risk.
- Consider homocysteine level, although treatment of hyperhomocysteinemia (vitamins $B_{12}$ and $B_6$, folate) does not alter the thrombophilic risk.

**Follow-Up Tests & Special Considerations**
Dysfibrinogenemia and plasminogen deficiency are very rare causes of thrombophilia.

---

**TREATMENT**

**MEDICATION**

**First Line**
- Newer oral anticoagulants: Apixaban, dabigatran, edoxaban, and rivaroxaban are now recommended over vitamin K antagonists for long-term oral anticoagulation (5)[B].
- May consider direct oral anticoagulants for patients with cancer, but data is lacking to recommend over LMWH
- Parenteral anticoagulation: LMWH has largely replaced UFH as first-line therapy for VTE.
  - Enoxaparin (Lovenox): 1 mg/kg SC BID for at least 5 days (with concomitant warfarin) until international normalized ratio (INR) has reached 2 for at least 24 hours; adjust dose for renal disease.
  - Enoxaparin is preferred in patients with active cancer for a minimum of 6 months (can dose at 1.5 mg/kg SC daily), after which time the patient can be reevaluated to continue treatment (4).
  - Adverse reactions: bleeding, heparin-induced thrombocytopenia (HIT) <0.5% incidence, bone loss (uncommon)
  - Reversal: Stop LMWH.
– UFH: 80 U/kg or 5,000 U IV bolus, then 18 U/kg/hr or 1,000 U/hr to target the activated partial thromboplastin time (aPTT) to a corresponding anti-Xa level of 0.3 to 0.7 U/mL. The first aPTT should be checked 6 hours after initial therapy and adjusted per standard heparin nomograms, aiming for an adequate level within 24 hours. Transition to warfarin is similar to the recommendations for enoxaparin.
  o SC UFH is an alternative and can be given as 5,000 U IV (once) followed by 250 U/kg SC BID, or 250 U/kg bolus followed by 250 U/kg BID (monitored as for IV UFH), or 333 U/kg once followed by 250 U/kg SC BID (unmonitored).
  o Adverse reactions: bleeding, HIT 3% incidence, bone loss (long-term use)
  o Reversal: Stop heparin and give protamine.

• Oral factor Xa inhibitors
  – Rivaroxaban (Xarelto): 15 mg BID for 21 days and then 20 mg once daily; not recommended in morbidly obese patients due to lack of data (5)[C]
  – Apixaban (Eliquis): 10 mg BID for 7 days and then 5 mg BID; can be used without need for preceding heparin therapy; less renal clearance than other oral anticoagulants
  – Edoxaban (Savaysa): 60 mg daily. Requires treatment with heparin for 5 days prior to initiation, needs adjustment for renal impairment. Not recommended if creatinine clearance >95 mL/min. Adjust dose to 30 mg in patients <60 kg or if using verapamil, quinidine, macrolides, or oral antifungals.

• Direct thrombin inhibitors
  – Dabigatran (Pradaxa): 150 mg BID after 5 to 10 days of parenteral anticoagulation.
  Reversal agent: idarucizumab (Andexanet); may be dialyzable (5)[C]

• Vitamin K antagonist
  – Warfarin (Coumadin): 10 mg/day initially and adjust to INR 2 to 3
  o Warfarin requires careful and frequent monitoring because of many drug–drug and drug–diet (e.g., vitamin K) interactions.
  o Adverse reactions: bleeding, skin necrosis (rare and early in course)
  o Reversal: four-factor prothrombin complex concentrate (PCC); fresh frozen plasma and/or vitamin K

• Pregnancy: low-dose aspirin and/or LMWH or UFH; warfarin is contraindicated.

Second Line
Usually indicated when contraindication to heparin or LMWH, such as heparin-associated thrombosis and thrombocytopenia, if there is an inability to use IV drugs, or renal failure. Direct oral anticoagulants may become first line as more clinical experience is developed.

• Factor Xa inhibitors
  – Fondaparinux (Arixtra): acute VTE/PE. Weight <50 kg: 5 mg/day SC; weight 50 to 100 kg: 7.5 mg/day SC; weight >100 kg: 10 mg/day SC; use for 5 to 9 days until oral anticoagulation is therapeutic.
  o Prophylaxis: 2.5 mg/day SC
  o Dose adjustments: needed for renal insufficiency; if creatinine clearance is <30 mL/min, use is contraindicated.

• Direct thrombin inhibitors:
  – Argatroban: liver metabolized; may be dose adjusted in liver dysfunction; therapeutic dose based on aPTT

SURGERY/OTHER PROCEDURES
Consider systemic thrombolysis for unstable cases (e.g., massive PE with hypotension).

- Inferior vena cava filter
  - Reduces short-term risk of PE in those with contraindications to anticoagulation (e.g., gastrointestinal bleeding, cerebral hemorrhage)
  - May increase long-term risk of recurrent DVT
  - Used for patients with multiple episodes of recurrent thromboembolism despite therapeutic anticoagulation and contraindication to anticoagulation

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Avoid significant risk for trauma (e.g., contact sports, climbing a ladder).

**Patient Monitoring**

Monitor warfarin as frequently as needed to maintain an INR goal of 2 to 3.

**Diet**

Vitamin K–stable diet if patient is taking warfarin

**Patient Education**

- Assume that any drug may enhance or attenuate the warfarin effect.
- Increase the frequency of monitoring following any medication change to ensure therapeutic anticoagulation and to avoid overanticoagulation, especially with antibiotics.
- Many drugs may modulate warfarin effect: alcohol, antibiotics, aspirin, NSAIDs, acetaminophen.

**Prognosis**

- Anticoagulation should be continued for 3 months with consideration for longer in those with unprovoked VTE.
- Patients with a provoked VTE (i.e., surgery, hospitalization) not receiving chronic anticoagulation have risks of recurrence of 7% (year 1), 16% (year 5), and 23% (year 10).
- Patients with an unprovoked VTE not receiving chronic anticoagulation have risks of recurrence of 15% (year 1), 41% (year 5), and 53% (year 10).
- Currently, there are no data from randomized controlled trials or controlled clinical trials about the benefits of thrombophilia testing to decrease the risk of recurrent VTE (1).

**Complications**

Venous or arterial thrombosis; bleeding in anticoagulated patients

**References**

ADDITIONAL READING

CODES

ICD10
- D68.59 Other primary thrombophilia
- D68.51 Activated protein C resistance
- D68.2 Hereditary deficiency of other clotting factors

CLINICAL PEARLS

- Factor V Leiden (resistance to aPC) is the most common inherited thrombophilia, with a prevalence of 2–7% in the U.S. Caucasian population.
- Test patients for thrombophilias only if it will affect management of the condition.
- Rule out malignancy, especially in those >50 years of age.
BASICS

DESCRIPTION

- An acute syndrome of microangiopathic hemolytic anemia (MAHA) and consumptive thrombocytopenia with deposition of hyaline thrombi in terminal arterioles and capillaries leading to ischemic multiorgan damage
- Thrombotic thrombocytopenic purpura (TTP) is characterized by MAHA (schistocytes on peripheral smear) and thrombocytopenia (generally <30 K), with or without the following signs and symptoms:
  - Neurologic symptoms
  - Renal dysfunction
  - Fever
  - Most patients do not show the historic pentad of MAHA, thrombocytopenia, renal dysfunction, neurologic abnormalities, and fever because treatment is initiated before the pentad can develop.

EPIDEMIOLOGY

Incidence

- First episode mostly in adulthood (~90%) and in 10% childhood to adolescence (1)
- Predominant sex: female > male (2:1), (1)
- Incidence ratio in blacks to whites is 7:1.
- Annual prevalence of ~10 cases per million people and an annual incidence of ~1 new case per million people (1)

ETIOLOGY AND PATHOPHYSIOLOGY

- In TTP, the aggregating agent responsible for platelet thrombi is unusually large von Willebrand factor (UL vWF) multimers, which are far larger than those found in normal plasma.
- A metalloproteinase, ADAMTS13, which normally enzymatically cleaves UL vWF multimers to prevent clumping within vessels, is deficient, defective, or absent, allowing UL vWF to react with platelets. This leads to the endothelial cell damage and disseminated thrombi characteristic of TTP.
- Arterioles most often affected are in the brain, kidney, pancreas, heart, and adrenal glands. Lungs and liver are relatively spared.
- In familial TTP, patients have an inherited deficiency of ADAMTS13.
- In acquired idiopathic TTP, autoantibodies are directed against the metalloproteinase ADAMTS13 (1,2).
- Endothelial injury, either directly from a drug/toxin or indirectly via platelet/neutrophil activation, has been proposed as a cause of secondary TTP especially in those without ADAMTS13 deficiency.
  - Drug induced (see “Risk Factors”)
Hematopoietic cell transplantation

Genetics
- TTP is most often an acquired disorder. A congenital form of inherited TTP (Upshaw-Schulman syndrome) is due to a mutation at the ADAMTS13 metalloproteinase gene locus on chromosome 9q34. This rare form of TTP has an autosomal-recessive pattern of inheritance.
- SUS typically presents in infancy and is rarely diagnosed after 10 years of age, it does not have the female predominance seen in idiopathic TTP, more often has notable renal impairment, and there is some heterogeneity among siblings, although parents who are carriers of a single heterozygous ADAMTS13 mutation are typically asymptomatic.

RISK FACTORS
- Pregnancy and oral contraceptives
- AIDS and early symptomatic HIV infection
- Bacterial infection/sepsis
- Acute pancreatitis
- Autoimmune disease
  - Antiphospholipid antibody syndrome
  - Systemic lupus erythematosus
  - Scleroderma
- Cancer
- Hematopoietic stem cell transplantation
- Solid organ transplant
- Drugs of abuse: MDMA, cocaine, oxymorphone ER
- Drug toxicity
  - Antimicrobials
    - Trimethoprim, ciprofloxacin, famciclovir
  - Cancer chemotherapy
    - Mitomycin C and gemcitabine
    - Pentostatin and vincristine
    - Bleomycin and cisplatin
    - Oxaliplatin
    - Bevacizumab and Sunitinib
    - Adalimumab
    - Bortezomib, carfilzomib, and ixazomib
  - Calcineurin inhibitors
    - Tacrolimus and cyclosporine
  - Immune mediated
    - Quinine and quinidine
    - Ticlopidine and clopidogrel

COMMONLY ASSOCIATED CONDITIONS
- TTP/hemolytic uremic syndrome (HUS)/atypical HUS have similar presentations with MAHA and thrombocytopenia and multiorgan involvement.
- TTP generally presents with minimal renal involvement and may have neurologic abnormalities, whereas the opposite is more characteristic of HUS/atypical HUS. Creatinine of >2.3 is suggestive against TTP.
However, patients with HUS and TTP may have both prominent renal and neurologic manifestations, often making the diagnosis unclear, hence the historical hybrid name “TTP-HUS.”

ADAMTS13 levels are diminished (generally <10%) in adults with familial or acquired idiopathic TTP but are normal in children diagnosed with HUS following infection with Escherichia coli (particularly type O157:H7), so-called Shiga toxin-HUS, and in “atypical HUS,” is also called complement-mediated thrombotic microangiopathy reflecting the pathophysiology which is related to complement dysregulation.

**DIAGNOSIS**

- Most common symptoms are nonspecific: nausea, vomiting, weakness, abdominal pain, fatigue, fever.
- Related to thrombocytopenia
  - Easy bruising, purpura, or petechiae
  - Epistaxis, menorrhagia, bleeding gums
  - GI bleeding
  - Intracranial hemorrhage
  - Visual symptoms due to retinal hemorrhage
- Related to hemolytic anemia (MAHA): jaundice, fatigue
- Related to end-organ ischemia
  - Neurologic: CNS symptoms occur in 50%.
    - Often fluctuating symptoms
    - Headache
    - Altered mental status: Spectrum runs from behavioral/personality changes—obtundation/stupor/coma.
    - Seizures, stroke
  - Renal: hematuria, oliguria, or anuria
  - Cardiac: arrhythmia, myocardial infarction, heart failure
- A scoring system (PLASMIC) devised to predict ADAMTS13 activity <10% in adults (to support the diagnosis of TTP); 1 point each for:
  - Platelet count <30,000/μL
  - Hemolysis (reticulocyte count >2.5%, undetectable haptoglobin, or indirect bilirubin >2 mg/dL)
  - No active cancer
  - No solid organ or stem cell transplant
  - MCV <90 fL
  - INR <1.5
  - Creatinine <2.0 mg/dL
- Score 6 to 7 predictive of ADAMTS13 activity of <10%. Score of 0 to 4 predictive of ADAMTS13 activity was not <10%.

**HISTORY**

- Generally acute onset of symptoms but subacute in about 1/4 of patients
- It is important to assess for potential underlying causes or risk factors (see discussion earlier).
- In about 50% of cases, a trigger/risk factor of some kind is identified (3).
PHYSICAL EXAM
- Fever
- Mental status/neurologic: confusion, coma, stupor, weakness
- HEENT: retinal hemorrhage, scleral icterus, epistaxis
- Abdomen/GI: nonspecific tenderness
- Skin: jaundice, petechiae, purpura, ecchymoses

DIFFERENTIAL DIAGNOSIS
- HUS and atypical HUS
- Antiphospholipid antibody syndrome: prolonged partial thromboplastin time (PTT) and presence of lupus anticoagulant
- Systemic lupus erythematosus
- Malignant hypertension (HTN): diastolic >130 mm Hg, papilledema, retinal hemorrhages
- Pregnancy-associated preeclampsia/eclampsia or hemolysis, elevated liver enzyme levels, and low platelet HELLP levels: low ATIII levels
- Disseminated intravascular coagulation
  - Prolonged prothrombin time (PT)/PTT, low fibrinogen, low factors V and VIII
  - Secondary to sepsis/shock or widely disseminated malignancy
- Idiopathic thrombocytopenic purpura (ITP)
  - No hemolysis, normal lactate dehydrogenase (LDH) and bilirubin
  - Presence of antiplatelet antibodies
- Malignancy-associated microangiopathy
- Evan syndrome (autoimmune hemolytic anemia and thrombocytopenia): positive direct Coombs test
- Sclerodermal kidney

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- CBC
  - Hemoglobin (decreased): Average is 8 to 10 g/dL.
  - Platelets decreased: in the 10 to 30,000 range
- High reticulocyte count (>120 × 10⁹/L)
- Undetectable haptoglobin (hemolysis)
- Peripheral smear
  - Schistocytes (prominent, >1% of RBCs)
  - Helmet cells, RBC fragments
  - Nucleated RBCs
  - Polychromasia (reticulocytosis)
- Coagulation studies
  - Normal in most; mild elevation in 15%
  - Fibrinogen normal
- Coombs test: negative direct Coombs test
- Electrolytes, BUN/creatinine: mild elevation of BUN and creatinine (creatinine <3 mg/dL)
- Liver function studies: increased indirect bilirubin (hemolysis)
- LDH: 5 to 10 times normal
- Urinalysis
  - Proteinuria, microscopic hematuria
– Positive dipstick for large blood but minimal RBCs on microscopic exam
– ECG changes (10%): sinus tachycardia, heart block
– Stool for Shiga toxin
– Increased troponin in 60% cases (>0.1 μg/L)
– HIV, hepatitis A, B, C testing: Exclude underlying viral precipitant.
– Pregnancy test
– Pretreatment ADAMTS13 activity level of <10% is useful in distinguishing acquired or familial TTP from other disorders.
– Head CT/MRI scan: in patients with mental status changes to rule out possible intracranial pathology

Test Interpretation
Biopsy of affected organs shows platelet thrombi; however, biopsy is rarely obtained because diagnosis is made on clinical and laboratory findings.

TREATMENT

ALERT
– Prompt treatment of TTP is necessary due to the high mortality (90%).
– Complete response to treatment is defined by a platelet count >150 × 10^9/L for 2 consecutive days, together with normal or normalizing LDH and clinical recovery (1).
– In the absence of another apparent cause, the dyad of MAHA and thrombocytopenia is sufficient to begin treatment for TTP while the workup proceeds (1,2):
  – Plasma exchange (PEX) transfusion is the cornerstone of treatment of TTP and should begin immediately (2)[A].
  – PEX replaces deficient or defective metalloproteinase (ADAMTS13) and removes UL vWF and antimalloproteinase antibodies.
  – Optimal PEX duration is variable. Convention is to continue for 2 days after platelet count is ≥150,000 and then consider tapering (4)[C].
  – Fresh frozen plasma: temporary measure until PEX can be initiated (2)[B]; should be reserved for those with active bleeding

MEDICATION
First Line
– Glucocorticoids has adjunctive benefit in some patients. British guidelines recommend its use for all patients (5)[B].
  – Steroids may work by suppressing the autoantibodies inhibiting ADAMTS13 activity.
  – Use may be in patients with severe ADAMTS13 deficiency, in the setting of exacerbation when PEX is stopped or in relapse after remission.
  – Little benefit of steroids when used as monotherapy
  – Doses: prednisone 1 to 2 mg/kg/day and taper once in remission or methylprednisolone 1 g/day IV for 3 days
– Rituximab, an anti-CD20 antibody that deletes B cells, may reduce relapse when given in conjunction with PEX and steroids.
  – Dose: 375 mg/m^2 IV weekly for 4 weeks
Second Line
The following medications are used in refractory cases:

- Rituximab (5)[B]
- Vincristine, cyclophosphamide, cyclosporine
- Intravenous immunoglobulin (IVIG) (2)
- Bortezomib (5)[C]
- Caplacizumab, an inhibitor of VWF-glycoprotein 1b interaction
- Jehovah’s witness patients can be treated with steroids plus rituximab.

 ISSUES FOR REFERRAL
- Hematology or blood bank for PEX
- Nephrology for dialysis
- Cardiology for presence of significant heart block or ischemia
- Neurosurgery for intracranial hemorrhage

 SURGERY/OTHER PROCEDURES
Splenectomy is reserved for severe, refractory cases (1).

 ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- ABCs, oxygen, IV access, telemetry
- Volume resuscitation if hypotensive/actively bleeding
- Packed RBCs can be transfused safely.
- Platelet transfusion may be used for the treatment of hemorrhage.
- Discharge on normalization and stabilization of neurologic symptoms, LDH, platelets, and renal function

 ONGOING CARE

 FOLLOW-UP RECOMMENDATIONS
- Maintenance therapy is not required. After PEX is discontinued, blood counts should be monitored for months. If results remain normal, testing interval can be lengthened.
- Promptly evaluate any relapse symptoms.

 PATIENT EDUCATION
- On discharge, advise patients to self-monitor for signs of relapse (e.g., fever, headache, bruising).
- Patients should be advised about prolonged periods of fatigue following the acute phase.
- See National Heart, Lung, and Blood Institute Web site: http://www.nhlbi.nih.gov/health/health-topics/topics/ttp

 PROGNOSIS
- Most recover fully from idiopathic TTP when treated promptly:
  - 30-day mortality is 10% in those who receive PEX.
  - 70% respond within 14 days; 90% respond within 28 days.
  - 80% survival in idiopathic TTP treated with PEX (1)
- Prior to widespread PEX treatment, TTP carried up to a 90% mortality rate.
- Initial LDH and platelet counts are not predictive of response to treatment.
• Final platelet count and LDH or the length or intensity of treatment does not predict relapse.
• Low levels of ADAMTS13 activity during remission are associated with higher risk of relapse (1).
• In patients with severe ADAMTS13 deficiency, the risk of relapse is estimated to be 41% at 7.5 years, with the greatest risk being in the 1st year.
• In patients with autoimmune TTP, there is a 40% relapse rate (3).

COMPLICATIONS
• Patients may experience mild cognitive impairments in attention, concentration, and memory following ≥1 episode of TTP.
• Complications of PEX include the following:
  – Central line infections and hemorrhage
  – Citrate toxicity
  – Hypersensitivity reactions to frequent plasma exposure
  – Electrolyte abnormalities

REFERENCES

ADDITIONAL READING

CODES
ICD10
- M31.1 Thrombotic microangiopathy
- D69.42 Congenital and hereditary thrombocytopenia purpura
- D69.3 Immune thrombocytopenic purpura

CLINICAL PEARLS
• The diagnosis of TTP is made clinically; common symptoms are nonspecific: nausea;
vomiting; weakness; abdominal pain; fatigue; fever; and easy bruising, purpura, or petechiae.

- The historical pentad of fever, neurologic symptoms, renal dysfunction, MAHA, and thrombocytopenia is not present in most patients.
- The dyad of MAHA (schistocytes on peripheral smear) and severe thrombocytopenia (<30 K) is sufficient to initiate treatment with PEX.
- Do not wait for results of ADAMTS13 determination to initiate therapy.
BASICS

DESCRIPTION
Thyroid malignant neoplasia is an uncontrolled proliferation of cells within the thyroid gland. There are several different types:

- **Papillary thyroid carcinoma (PTC)**
  - Differentiated tumor with papillary cells with finger-like projections
  - Most common variety, 75–80% of thyroid cancers
  - Peak incidence in the 3rd or 4th decade of life
  - Approximately 3 times more common in women
  - Associated with radiation exposure
  - Metastasizes by lymphatic route (15–30% have palpable lymphadenopathy at time of diagnosis)
  - Multicentric in ≥20%, especially in children
  - Increasing incidence may be due to increased diagnosis of smaller size tumors.
  - Many subtypes: conventional, follicular variant, oxyphilic, cribriform-morular, and more aggressive forms such as tall cell or diffuse sclerosing

- **Follicular carcinoma**
  - Differentiated tumor with spherical follicular cells
  - Second most common variety, 10–20% of thyroid tumors
  - Peak incidence in 5th decade of life
  - Metastasizes by the hematogenous route
  - Can be divided into invasive and minimally invasive forms based on morphology

- **Hürthle cell carcinoma** (variant of follicular with poorer prognosis)
  - Often considered subtype of FTC with overall poorer prognosis
  - Also known as oncocytic or oxyphilic carcinoma
  - 2–3% of thyroid malignancies
  - Usually in patients >60 years old
  - Often radioresistant

- **Medullary thyroid carcinoma (MTC)**
  - Neuroendocrine tumor arising from parafollicular C cells
  - 3–4% of all thyroid carcinoma
  - 75–80% sporadic and occurs as isolated disease
  - 25–35% are associated with multiple endocrine neoplasia (MEN) syndromes, which can be familial or sporadic.
  - MTC associated with MEN2B occur in childhood, those with MEN2A occur in young adults, and those with familial non-MEN medullary thyroid cancer (FMTC) occur in middle age.
  - Calcitonin is a serologic marker.
  - RET proto-oncogene mutation is used for screening; family members who carry the RET
gene should consider early prophylactic thyroidectomy.

- **Anaplastic carcinoma**
  - Undifferentiated tumor arising de novo or from dedifferentiation of preexisting differentiated thyroid carcinoma
  - 1–3% of thyroid tumors
  - Most aggressive form of thyroid neoplasia due to rapid growth, locoregional invasion, and metastases
  - Almost uniformly fatal (median survival 2 to 6 months)
  - More common in elderly patients

- **Poorly differentiated thyroid carcinoma (PDTC)**
  - Intermediate between differentiated (follicular and papillary carcinomas) and undifferentiated (anaplastic) carcinomas
  - Aggressive tumor similar to anaplastic carcinoma, but may have better treatment response

- **Other:** lymphoma, sarcoma, or metastatic (renal, breast, or lung)

- **System(s) affected:** endocrine/metabolic
- **Synonym(s):** well-differentiated, poorly differentiated, and undifferentiated thyroid carcinoma

### Geriatric Considerations
Risk of malignancy (ROM) increases, and prognosis is worse >60 years old.

### Pediatric Considerations
- Thyroid nodules are more frequently malignant (22–25% in children vs. 5–10% in adults).
- <2% of thyroid malignancies occur in children and adolescents.
- Increased tumor size (>4 cm), extrathyroidal extension, and multifocal disease are independent factors associated with nodal metastases in pediatric differentiated thyroid cancer and require further evaluation with FNA for suspicious nodes to consider neck dissection (1)[C].

### EPIDEMIOLOGY
- Incidence: 14.5/100,000 per year in the United States
- Deaths: 0.5/100,000 per year in the United States
- In 2018, estimated 53,990 new cases and 2,060 deaths from thyroid cancer in the United States
- Predominant age: usually >40 years old
- Predominant sex: female > male (3:1) prevalence
- Lifetime risk of developing thyroid cancer is 1.2%.
- In 2015, 765,547 patients living with thyroid cancer in the United States

### ETIOLOGY AND PATHOPHYSIOLOGY
- No established etiologic factors of pathogenesis; most cases arise spontaneously.
- Radiation exposure likely has a role in the development of thyroid malignancies.
- Gene mutations that activate the MAPK pathway (e.g., BRAF) and PI3K-AKT pathway (e.g., PTEN) have been implicated.

### Genetics
- Familial polyposis of the colon, Gardner syndrome with the APC gene (5q21), and Cowden syndrome
- MTC: autosomal dominant with MEN syndrome
- Medullary: autosomal dominant with MEN syndrome
- BRAF mutation (rare in children) in PTC
- RAS mutations in FTC
- RET oncogene (more common in children) in MTC and PTC
- TP53 mutation in ATC

**RISK FACTORS**
- Family history (first-degree relative)
- Radiation exposure: papillary carcinoma
- Iodine deficiency: follicular carcinoma
- MEN2: medullary carcinoma; autosomal dominant inheritance; RET proto-oncogene
- Previous history of subtotal thyroidectomy for malignancy: anaplastic carcinoma
- Female gender

**GENERAL PREVENTION**
- Physical exam in high-risk group
- Calcitonin stimulation screening in high-risk MEN patients
- Screening for RET proto-oncogene in groups at risk for MTC

**COMMONLY ASSOCIATED CONDITIONS**
- Papillary carcinoma: Hashimoto thyroiditis
- Medullary carcinoma: pheochromocytoma, hyperparathyroidism, ganglioneuroma of the GI tract, neuromata of mucosal membranes

**DIAGNOSIS**

**HISTORY**
- Change in voice (dysphonia)
- Difficulty swallowing (dysphagia)
- Difficulty breathing (dyspnea)
- Stridor (in aggressive cancer)
- Growing neck mass
- Positive family history
- History of radiation exposure (environmental or radiation therapy for childhood cancer)

**PHYSICAL EXAM**
- Thyroid nodule/mass
- Fixation to surrounding tissues suggests malignancy.
- Cervical lymphadenopathy

**DIFFERENTIAL DIAGNOSIS**
- Multinodular goiter
- Thyroid adenoma
- Thyroglossal duct or dermoid cyst
- Thyroiditis
- Thyroid cyst
- Ectopic thyroid

**DIAGNOSTIC TESTS & INTERPRETATION**
Initial Tests (lab, imaging)

- Ultrasound (US): Nodule characteristics suggestive of malignancy include hypoechoic pattern, microcalcifications, irregular margins, and shape taller than wide \(2\).[A]
- Thyroid-stimulating hormone (TSH): usually normal in the setting of malignancy but recommended for all nodule workup

Follow-Up Tests & Special Considerations

- CT and MRI neck: useful to evaluate large substernal masses, extent of invasion for fixed bulky tumors, if suspicion of MTC with neck disease or calcitonin >400 pg/mL, and to evaluate for recurrent disease
- Calcitonin levels: Measure in patients with FNA results or with personal or family history of MEN2 syndrome suggestive of MTC (consider IV pentagastrin stimulation test to increase sensitivity).
- RET proto-oncogene gene analysis: if concerned for MTC
- Thyroid scan: 12–15% of cold nodules are malignant; rate is higher in patients <40 years of age and those with microcalcifications on US. \(^{18}\)F-FDG positron-emission tomographic scan can help if the cytology is indeterminant; also helpful with recurrent disease when patient has a negative \(^{131}\)I scan and an elevated thyroglobulin (TG) level \(3\).[B]
- TG: not recommended in initial evaluation but used as postoperative tumor marker for recurrence

Diagnostic Procedures/Other

- Fine-needle aspiration biopsy (FNAB)
- Flexible fiberoptic laryngoscopy: if vocal cord paralysis is suspected and in high-risk disease

Test Interpretation

- FNAB: The 2017 Bethesda System for Reporting Thyroid Cytopathology classification of cytology
  - Nondiagnostic or unsatisfactory
  - Benign: 0–3% ROM
  - Atypia of undetermined significance (AUS) or follicular lesion of undetermined significance (FLUS): 10–30% ROM
  - Follicular neoplasm or suspicious for a follicular neoplasm: 25–40% ROM
  - Suspicious for malignancy: 50–75% ROM
  - Malignant: 97–99% ROM
- Papillary: psammoma bodies, anaplastic epithelial papillae
- Follicular: anaplastic epithelial cords with follicles
- Hürthle cell: large eosinophilic cells with granular cytoplasm
- Medullary: large amounts of amyloid stroma
- Anaplastic: small cell and giant cell undifferentiated tumors

TREATMENT

GENERAL MEASURES

- Most cases of thyroid cancer are managed surgically and medically with a good prognosis \(2\).[A]
Palliative support has a role in case of advanced thyroid malignancy (4)[C].

Papillary and follicular: $^{131}I$ thyroid remnant ablation

Medullary: Vandetanib, and other tyrosine kinase inhibitors, have been tried in patients with advanced disease (5)[B].

Anaplastic: Doxorubicin and cisplatin have achieved partial remission in some patients.

**MEDICATION**

Postoperatively, will require thyroid hormone replacement after total thyroidectomy

- Thyroxine suppression therapy may reduce recurrence with goal to keep TSH <0.1 mU/L for high-risk patients, 0.1 to 0.5 mU/L for intermediate-risk patients, and 0.5 to 2.0 mU/L for low-risk patients (2)[A].

Levothyroxine (T$_4$, Synthroid)

Liothyronine (T$_3$, Cytomel)

**ADDITIONAL THERAPIES**

- External beam radiation or chemotherapy may be considered for radioactive iodine insensitive tumors, inoperable recurrence, and for palliative care.

$^{131}I$ is used in high-risk patients with papillary and follicular tumors. The role is to ablate remnant thyroid tissue to improve specificity of future TG assays to monitor for recurrence. Patients are taken off thyroid suppression therapy for 2 to 4 weeks before scanning and are often placed on a low-iodine diet for 14 days prior to therapy.

**SURGERY/OTHER PROCEDURES**

- Papillary: total thyroidectomy with elective neck dissection for suspicious lymph nodes in central or lateral neck compartments or for large tumors (>4 cm in size). Lobectomy with isthmectomy can be considered if lesion <1 cm in low-risk patient (controversial).

- Follicular and Hürthle cell: similar management as papillary carcinoma

- Medullary: total thyroidectomy with central node dissection; unilateral or bilateral modified radical neck dissection if lateral nodes are suspicious

- Anaplastic: palliative care; no adequate treatment available and surgery is controversial. Consider tracheostomy (protect airway) and clinical trials utilizing chemotherapy/radiation.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- 10–30% of initially disease-free patients will develop recurrence and/or metastases. 80% recur in neck and 20% with distant metastases. Lung is most common site of distant metastases.

- TSH, TG, and anti-TG antibodies at 6 months, 12 months, and then yearly after that for surveillance (6)[C]

- Periodic US to monitor for recurrence is recommended in intermediate- to high-risk patients and may also consider TSH-stimulated radioiodine whole body imaging in high-risk patients (6)[C].

- Medullary: Calcitonin level should be done yearly with pentagastrin stimulation.

- The thyroid scan and TG level should be done with the patient in the hypothyroid state induced
by 6-week withdrawal of levothyroxine or 2- to 3-week withdrawal of liothyronine.

**DIET**

Low-iodine diet recommended in patients undergoing radioactive iodine therapy following surgery for thyroid cancer.

**PATIENT EDUCATION**

- American Thyroid Association: [https://www.thyroid.org/thyroid-information/](https://www.thyroid.org/thyroid-information/)

**PROGNOSIS**

- 5-year survival of thyroid cancer is 98.1%.
- Adverse factors: age >45 years, primary tumor >4 cm, extrathyroid extension, distant metastases
- Low risk: no extrathyroidal invasion, all macroscopic tumor resected, no local or distant metastases, no vascular invasion, and no aggressive tumor histology
- Intermediate risk: microscopic extrathyroidal invasion, cervical lymph node metastases on $^{131}$I update outside of thyroid bed on first whole body after remnant ablation
- High risk: macroscopic extrathyroidal tumor invasion, incomplete tumor resection, distant metastases
- Papillary carcinoma: 10-year overall survival is 93%; 30-year cancer-related death rate of 6%
- Follicular carcinoma: 10-year overall survival is 85%; histologically, microinvasive tumors parallel papillary tumor results, whereas grossly invasive tumors do far worse; 30-year cancer-related death rate of 15%
- Hürthle cell carcinoma: 93% 5-year survival rate and 83% survival rate overall; grossly invasive tumor survival <25%
- Medullary carcinoma: negative nodes, 90% 5-year survival rate and 85% 10-year survival rate; with positive nodes, 65% 5-year survival rate and 40% 10-year survival rate. Prognosis worse for MEN2B compared to MEN2A. Overall, 10-year survival is 75%.
- Anaplastic carcinoma: survival unexpected. Long-term survivors should have original pathology reexamined.

**COMPPLICATIONS**

- Hoarseness either from tumor invasion or iatrogenic injury to recurrent laryngeal nerve
- Hypocalcemia/hypoparathyroidism from devascularization of parathyroid glands during surgery (usually transient)

**REFERENCES**

SEE ALSO
Multiple Endocrine Neoplasia (MEN) Syndromes

CODES
ICD10
C73 Malignant neoplasm of thyroid gland

CLINICAL PEARLS

- Standard workup for a patient suspected of having a thyroid cancer is a physical exam, TSH level, neck US, and FNA.
- TG levels can be elevated in several thyroid disorders. Its usefulness comes once the diagnosis of cancer has been made. It serves as a better marker for recurrent disease.
- FNA results will be benign, malignant, indeterminate, or nondiagnostic. It is very helpful in guiding the initial surgical approach.
**THYROIDITIS**
Pradeepa P. Vimalachandran, MD, MPH

---

**BASICS**

**DESCRIPTION**

Inflammation of the thyroid gland that may be painful or painless and characterized by dysfunction

- **Thyroiditis with thyroid pain include**
  - Subacute granulomatous thyroiditis (nonsuppurative thyroiditis, de Quervain thyroiditis, or giant cell thyroiditis): self-limited; viral URI prodrome, symptoms and signs of thyroid dysfunction (variable)
  - Infectious/suppurative thyroiditis
    - Can be due to bacterial, fungal, mycobacterial, or parasitic infection of the thyroid
  - Most commonly associated with Streptococcus pyogenes, Staphylococcus aureus, and Streptococcus pneumoniae
    - Radiation-induced thyroiditis: from radioactive iodine therapy (1%) or external irradiation for lymphoma and head/neck cancers

- **Thyroiditis with no thyroid pain include**
  - Hashimoto (autoimmune) thyroiditis (chronic lymphocytic thyroiditis): most common etiology of chronic hypothyroidism; autoimmune disease; 90% of patients with high-serum anti-thyroid peroxidase (TPO) antibodies
  - Postpartum thyroiditis: episode of thyrotoxicosis, hypothyroidism, or thyrotoxicosis followed by hypothyroidism in the 1st year postpartum or after spontaneous/induced abortion in women who were without clinically evident thyroid disease before pregnancy
  - Painless (silent) thyroiditis (subacute lymphocytic thyroiditis): mild hyperthyroidism, small painless goiter, and no Graves ophthalmopathy/pretibial myxedema
  - Riedel (fibrous) thyroiditis: rare inflammatory process involving the thyroid and surrounding cervical tissues; associated with various forms of systemic fibrosis; presents as a firm mass in the thyroid commonly associated with compressive symptoms (dyspnea, dysphagia, hoarseness, and aphonia) caused by local infiltration of the advancing fibrotic process with hypocalcemia and hypothyroidism
  - Drug-induced thyroiditis: interferon-α, interleukin-2, amiodarone, kinase inhibitors, or lithium

**EPIDEMIOLOGY**

- Subacute granulomatous thyroiditis: most common cause of thyroid pain; peaks during summer; incidence: 3/100,000/year; female > male (4:1); peak age: 40 to 50 years
- Suppurative thyroiditis: commonly seen with preexisting thyroid disease/immunocompromise
- Hashimoto thyroiditis: peak age of onset, 30 to 50 years; can occur in children; primarily a disease of women; female > male (7:1)
- Postpartum thyroiditis: female only; occurs within 12 months of pregnancy in 8–11% of pregnancies; occurs in 25% with type 1 diabetes mellitus; incidence is affected by genetic influences and iodine intake.
- Painless (silent) thyroiditis: accounts for 1–5% of cases; female > male (4:1) with peak age 30
ETIOLOGY AND PATHOPHYSIOLOGY

- Hashimoto disease: Antithyroid antibodies may be produced in response to an environmental antigen and cross-react with thyroid proteins (molecular mimicry). Precipitating factors include infection, stress, sex steroids, pregnancy, iodine intake, and radiation exposure.
- Subacute granulomatous thyroiditis: probably viral
- Postpartum thyroiditis: autoimmunity-induced discharge of preformed hormone from the thyroid
- Painless (silent) thyroiditis: autoimmune

Genetics
Autoimmune thyroiditis is associated with the CT60 polymorphism of cytotoxic T-cell lymphocyte–associated antigen 4; also associated with HLA-DR4, HLA-DR5, and HLA-DR6 in whites

RISK FACTORS

- Hashimoto disease: family history of thyroid/autoimmune disease, personal history of autoimmune disease (type 1 diabetes, celiac disease), high iodine intake, cigarette smoking, selenium deficiency
- Subacute granulomatous thyroiditis: recent viral respiratory infection or HLA-B35
- Suppurative thyroiditis: congenital abnormalities (persistent thyroglossal duct/pyriform sinus fistula), greater age, immunosuppression
- Radiation-induced thyroiditis: high-dose irradiation, younger age, female sex, preexisting hypothyroidism
- Postpartum thyroiditis: smoking, history of spontaneous/induced abortion
- Painless (silent) thyroiditis: iodine-deficient areas

GENERAL PREVENTION
Selenium may decrease inflammatory activity in pregnant women with autoimmune hypothyroidism and may reduce postpartum thyroiditis risk in those positive for TPO antibodies.

COMMONLY ASSOCIATED CONDITIONS
Postpartum thyroiditis: family history of autoimmune thyroid disease; HLA-DRB, HLA-DR4, and HLA-DR5

DIAGNOSIS

HISTORY

- Hypothyroid symptoms (e.g., constipation, heavy menstrual bleeding, fatigue, weakness, dry skin, hair loss, cold intolerance)
- Hyperthyroid symptoms (e.g., irritability, heat intolerance, increased sweating, palpitations, loose stools, disturbed sleep, and lid retraction)
- Subacute granulomatous thyroiditis: sudden/gradual onset, with preceding upper respiratory infection/viral illness (fever, fatigue, malaise, anorexia, and myalgia are common); pain may be limited to thyroid region or radiate to upper neck, jaw, throat, or ears.
Classic triphasic course (thyrotoxic, hypothyroid, recovery) but variable in the following: subacute, silent, and postpartum thyroiditis [1][C]

PHYSICAL EXAM
- Examine thyroid size, symmetry, and nodules.
  - Hashimoto disease: 90% have a symmetric, diffusely enlarged, painless gland, with a firm, pebbly texture; 10% have thyroid atrophy.
  - Postpartum thyroiditis: painless, small, nontender, firm goiter (2 to 6 months after delivery)
  - Reidel thyroiditis: rock-hard, wood-like, fixed, painless goiter, often accompanied by symptoms of esophageal/tracheal compression (stridor, dyspnea, a suffocating feeling, dysphagia, and hoarseness)
- Signs of hypothyroid: delayed relaxation phase of deep tendon reflexes, nonpitting edema, dry skin, alopecia, bradycardia
- Signs of hyperthyroid: moist palms, hyperreflexia, tachycardia/atrial fibrillation

DIFFERENTIAL DIAGNOSIS
Simple goiter; iodine-deficient/lithium-induced goiter; Graves disease; lymphoma; acute infectious thyroiditis; oropharynx and trachea infections; thyroid cancer; amiodarone; contrast dye; amyloid

DIAGNOSTIC TESTS & INTERPRETATION
- Thyroid-stimulating hormone (TSH), anti-TPO antibodies
  - Hashimoto disease
    - High titers of anti-TPO antibodies
    - New subtype: IgG4 thyroiditis, which is histopathologically characterized by lymphoplasmacytic infiltration, fibrosis, increased numbers of IgG4-positive plasma cells, and high-serum IgG4 levels; more closely associated with rapid progress, subclinical hypothyroidism, higher levels of circulating antibodies, and more diffuse low echogenicity [2][C]
  - Subacute granulomatous thyroiditis
    - High T₄, T₃; low TSH during early stages and elevated later; TSH varies with phase [1][C].
    - High thyroglobulin; normal levels of anti-TPO and antithyroglobulin antibodies (present in 25%, usually low titers)
    - Elevated erythrocyte sedimentation rate (ESR) (usually >50 mm/hr) and C-reactive protein; mild anemia and slight leukocytosis; LFTs are frequently abnormal during initial hyperthyroid phase and resolve over 1 to 2 months.
  - Suppurative thyroiditis
    - In the absence of preexisting thyroid disease, thyroid function is normal, but hyper-/hypothyroidism may occur.
    - Elevated ESR and WBC with marked increase in left shift
    - Fine-needle aspiration (FNA) of the lesion with Gram stain and culture is the most useful diagnostic test.
- Postpartum thyroiditis [3][B]
  - Anti-TPO antibody positivity is the most useful marker for the prediction of postpartum thyroid dysfunction.
  - Women known to be anti-TPO-Ab+ should have TSH measured at 6 to 12 weeks’ gestation and at 6 months postpartum or as clinically indicated.
– Thyrotoxic phase occurs 1 and 6 months postpartum (most commonly at 3 months) and usually lasts only 1 to 2 months.
– Hypothyroidism occurs between 3 and 8 months (most commonly at 6 months).
– Most patients (80%) have normal thyroid function at 1 year; 30–50% of patients develop permanent hypothyroidism within 9 years.
– High thyroglobulin, normal ESR

- Painless (silent) thyroiditis
  - Hyperthyroid state in 5–20%; averages 3 to 4 months, and total duration of illness is <1 year, followed by hypothyroidism and then a return to normal state; some have primary/subclinical hypothyroidism.
  - ~50% have anti-TPO antibodies (1)[C].

- Reidel thyroiditis (4)[C]
  - Hypothyroidism due to extensive replacement of the gland by scar tissue. Anti-TPO antibodies are present in 2/3 of patients along with low radioactive iodine uptake (RAIU).

- Drug-induced thyroiditis
  - Hyper-/hypothyroidism, low RAIU, and variable presence of anti-TPO antibodies

- US: shows variable heterogeneous texture, hypoechoic in subacute, painless (silent), and postpartum thyroiditis

- Thyroid RAIU scan: decreased in all forms of thyroiditis but not helpful in establishing diagnosis of Hashimoto disease; high RAIU in hashitoxicosis, Graves disease

- Random urine iodine measurement may be helpful to distinguish from other causes of low RAIU.
  - Urine iodine <500 μg/L (subacute granulomatous thyroiditis)
  - Urine iodine >1,000 μg/L (in patients with exposure to excess exogenous iodine/radiocontrast material)

Diagnostic Procedures/Other
- Hashimoto with a dominant nodule should have FNA to rule out thyroid carcinoma.
- Open biopsy is necessary for a definitive diagnosis of Reidel thyroiditis.

Test Interpretation
- Hashimoto disease: lymphocytic infiltration with formation of Askanazy (Hürthle) cells, oxyphilic changes in follicular cells, fibrosis, thyroid atrophy
- Subacute granulomatous thyroiditis: giant cells, mononuclear cell (granulomatous) infiltrate
- Postpartum thyroiditis: lymphocytic infiltration, occasional germinal centers, disruption and collapse of thyroid follicles
- Painless (silent) thyroiditis: lymphocytic infiltration, but without fibrosis, Askanazy cells, and extensive lymphoid follicle formation

TREATMENT

GENERAL MEASURES
Analgesics for pain; corticosteroids for severe granulomatous thyroiditis

MEDICATION
- Hashimoto disease (2)[C]
  - If hypothyroid/goitrous: levothyroxine (1.7 μg/kg/day for adults <50 years of age); if no
cardiac complications and no adrenal insufficiency, 1/2 replacement dose and increase to full replacement in 10 days
  o If >50 years of age or heart disease and/or adrenal insufficiency, begin with 25 μg/day and titrate to TSH of lower limit normal range.
• If thyrotoxic and symptomatic: propylthiouracil and propranolol
• An elevated TSH level in a woman who is pregnant or attempting to become pregnant is an indication for thyroid replacement.
• Subacute granulomatous thyroiditis
  – Anti-inflammatory agents for 2 to 8 weeks (NSAIDs or aspirin)
  – Pain with no improvement in 2 to 3 days after NSAID use: prednisone 40 mg/day; should result in pain relief in 1 to 2 days; if not, question diagnosis.
  – Severe pain: prednisone 40 to 60 mg/day discontinued over 4 to 6 weeks. If pain recurs, increase dose for several weeks and then taper.
  – Symptomatic hyperthyroidism: β-blockers while thyrotoxic (propranolol 40 to 120 mg/day)
  – Symptomatic hypothyroid phase: Levothyroxine, as mentioned earlier, target TSH in the normal range.
• Suppurative thyroiditis
  – Parenteral empiric, broad-spectrum antibiotics, and surgical drainage
• Painless (silent) thyroiditis
  – No treatment needed
  – If symptomatic during hyperthyroid state, treat with β-blocker (propranolol 40 to 120 mg/day).
  – Prednisone shortens the period of hyperthyroidism. Monitor TSH every 4 to 8 weeks to confirm resolution.
  – Treat hypothyroid symptoms and asymptomatic patients with TSH >10 mU/L with levothyroxine (50 to 100 μg/day), to be discontinued after 3 to 6 months.
• Postpartum thyroiditis (5)[C]
  – Treat symptomatic hyper-/hypothyroid state. Most do not need treatment.
  – Caution in breastfeeding mothers because β-blockers are secreted into breast milk.
  – For symptomatic hypothyroidism, treat with levothyroxine. Otherwise, remonitor in 4 to 8 weeks. Taper replacement hormone after 6 months if thyroid function has normalized.
• Reidel thyroiditis (4)[C]
  – Corticosteroids in early stages but controversial thereafter; prednisone 10 to 20 mg/day for 4 to 6 months, possibly continued thereafter if effective
  – Long-term anti-inflammatory medications to arrest progression and maintain a symptom-free course
  – Tamoxifen 10 to 20 mg BID as monotherapy or in conjunction with prednisone reduces mass size and clinical symptoms.
  – Methotrexate is used with some success.
  – Reduction of goiter seen with a combination of mycophenolate mofetil (1 g BID) and 100 mg/day prednisone
  – Debulking surgery is limited to isthmusectomy to relieve constrictive pressure when total thyroidectomy is not possible.
• Drug-induced thyroiditis
  – Discontinue offending drug.

SURGERY/OTHER PROCEDURES
Enlarged painful thyroid or tracheal compression

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Hashimoto disease: Repeat thyroid function tests every 3 to 12 months.
- Subacute granulomatous thyroiditis: Repeat thyroid function tests every 3 to 6 weeks until euthyroid and then every 6 to 12 months.
- Postpartum thyroiditis: Check TSH annually.
- Reidel thyroiditis: CT of cervical mediastinal region is recommended.
- TSH every 6 months in patients on amiodarone

Pregnancy Considerations
- Avoid radioisotope scanning if possible.
- Keep TSH maximally suppressed.
- If using RAIU scan, discard breast milk for 2 days because RAI is secreted in breast milk.

PROGNOSIS
- Hashimoto disease: persistent goiter; eventual thyroid failure
- Subacute granulomatous thyroiditis: 5–15% hypothyroid beyond a year: Some with eventual return to normal; remission may be slower in the elderly; recurrence rate: 1–4% after a year
- Painless (silent) thyroiditis: 10–20% hypothyroid beyond a year; recurrence rate 5–10% (much higher in Japan)
- Postpartum thyroiditis: 15–50% hypothyroid beyond a year; women may be euthyroid/continue to be hypothyroid at the end of 1st postpartum year. 70% recurrence rate in subsequent pregnancies; substantial risk exists for later development of hypothyroidism/goiter.

SEE ALSO

Hyperthyroidism; Hypothyroidism, Adult

CODES

ICD10

- E06.9 Thyroiditis, unspecified
- E06.1 Subacute thyroiditis
- E06.0 Acute thyroiditis

CLINICAL PEARLS

- TSH elevation above the normal range indicates a hypothyroid state; suppressed TSH indicates hyperthyroid state. Follow up with free T₃/T₄ determination.
- Follow patients on thyroid replacement with periodic TSH level.
TINEA (CAPITIS, CORPORIS, CRURIS)
Elisabeth L. Backer, MD

BASICS

DESCRIPTION
- Superficial fungal infections of the skin/scalp; various forms of dermatophytosis; the names relate to the particular area affected (1).
  - Tinea cruris: infection of crural fold and gluteal cleft
  - Tinea corporis: infection involving the face, trunk, and/or extremities; often presents with ring-shaped lesions, hence the misnomer ringworm
  - Tinea capitis: infection of the scalp and hair; affected areas of the scalp can show characteristic black dots resulting from broken hairs.
- Dermatophytes have the ability to subsist on protein, namely keratin.
- They cause disease in keratin-rich structures such as skin, nails, and hair.
- Infections result from contact with infected persons/animals.
  - Zoophilic infections are acquired from animals.
  - Anthropophilic infections are acquired from personal contact (e.g., wrestling) or fomites.
  - Geophilic infections are acquired from the soil.
- System(s) affected: skin, exocrine
- Synonym(s): jock itch; ringworm

EPIDEMIOLOGY

Incidence
- Tinea cruris
  - Predominant age: any age; rare in children
  - Predominant sex: male > female
- Tinea corporis
  - Predominant age: all ages
  - Predominant sex: male = female
- Tinea capitis
  - Predominant age: 3 to 9 years; almost always occurs in young children
  - Predominant sex: male = female

Prevalence
Common worldwide

Pediatric Considerations
- Tinea cruris is rare prior to puberty.
- Tinea capitis is common in young children.

Geriatric Considerations
Tinea cruris is more common in the geriatric population due to an increase in risk factors.

Pregnancy Considerations
Tinea cruris and capitis are rare in pregnancy.
ETIOLOGY AND PATHOPHYSIOLOGY
Superficial fungal infection of skin/scalp
- Tinea cruris: Source of infection is usually the patient’s own tinea pedis, with agent being transferred from the foot to the groin via the underwear when dressing; most common causative dermatophyte is Trichophyton rubrum; rare cases caused by Epidermophyton floccosum and Trichophyton mentagrophytes
- Tinea corporis: most commonly caused by T. rubrum; Trichophyton tonsurans most often found in patients with tinea gladiatorum
- Tinea capitis: T. tonsurans found in 90% and Microsporum sp. in 10% of patients

Genetics
Evidence suggests a genetic susceptibility in certain individuals.

RISK FACTORS
- Warm climates; summer months and/or copious sweating; wearing wet clothing/multiple layers (tinea cruris)
- Daycare centers/schools/confined quarters (tinea corporis and capitis)
- Depression of cell-mediated immune response (e.g., individuals with atopy or AIDS)
- Obesity (tinea cruris and corporis)
- Direct contact with an active lesion on a human, an animal, or rarely, from soil; working with animals (tinea corporis)

GENERAL PREVENTION
- Avoidance of risk factors, such as contact with suspicious lesions
- Fluconazole or itraconazole may be useful in wrestlers to prevent outbreaks during competitive season.

COMMONLY ASSOCIATED CONDITIONS
Tinea pedis, tinea barbae, tinea manus

DIAGNOSIS
HISTORY
- Lesions range from asymptomatic to pruritic.
- In tinea cruris, acute inflammation may result from wearing occlusive clothing; chronic scratching may result in an eczematous appearance.
- Previous application of topical steroids, especially in tinea cruris and corporis, may alter the overall appearance causing a more extensive eruption with irregular borders and erythematous papules. This modified form is called tinea incognito.

PHYSICAL EXAM
- Tinea cruris: well-marginated, erythematous, half-moon–shaped plaques in crural folds that spread to medial thighs; advancing border is well defined, often with fine scaling and sometimes vesicular eruptions. Lesions are usually bilateral and do not include scrotum/penis (unlike with Candida infections) but may migrate to perineum, perianal area, and gluteal cleft and onto the buttocks in chronic/progressive cases. The area may be hyperpigmented on resolution.
- Tinea corporis: scaling, round or oval pruritic plaques characterized by a sharply defined annular pattern with peripheral activity and central clearing (ring-shaped lesions); papules and occasionally pustules/vesicles present at border and, less commonly, in center.

- Tinea capitis: commonly begins with round patches of scale (alopecia less common). In its later stages, the infection frequently takes on patterns of chronic scaling with either little/marked inflammation or alopecia. Less often, patients will present with multiple patches of alopecia and the characteristic black-dot appearance of broken hairs. Extreme inflammation results in kerion formation (exudative, pustular nodulation).

**DIFFERENTIAL DIAGNOSIS**

- Tinea cruris
  - Intertrigo: inflammatory process of moist-opposed skin folds, often including infection with bacteria, yeast, and fungi; painful longitudinal fissures may occur in skin folds.
  - Erythrasma: diffuse brown, scaly, noninflammatory plaque with irregular borders, often involving groin; caused by bacterial infection with Corynebacterium minutissimum; fluoresces coral red with Wood lamp
  - Seborrheic dermatitis of groin
  - Psoriasis of groin (“inverse psoriasis”)
  - Candidiasis of groin (typically involves the scrotum)
  - Acanthosis nigricans

- Tinea capitis
  - Psoriasis
  - Seborrheic dermatitis
  - Pyoderma
  - Alopecia areata and trichotillomania
  - Aplasia cutis congenital

- Tinea corporis
  - Pityriasis rosea
  - Eczema (nummular)
  - Contact dermatitis
  - Syphilis
  - Psoriasis
  - Seborrheic dermatitis
  - Subacute systemic lupus erythematosus (SLE)
  - Erythema annulare centrifugum
  - Erythema multiforme; erythema migrans
  - Impetigo circinatum
  - Granuloma annulare

**DIAGNOSTIC TESTS & INTERPRETATION**

Wood lamp exam reveals no fluorescence in most cases (Trichophyton sp.); 10% of infections, those caused by T. rubrum, will fluoresce with a green light.

**Initial Tests (lab, imaging)**

- Potassium hydroxide (KOH) preparation of skin scrapings from dermatophyte leading border shows characteristic translucent, branching, rod-shaped hyphae.

- Arthrosopes can be visualized within hair shafts. Spores and/or hyphae may be seen on KOH
Follow-Up Tests & Special Considerations
- Reevaluate to assess response, especially in resistant/extensive cases.
- Fungal culture using Sabouraud dextrose agar/dermatophyte test medium

Test Interpretation
- Skin scrapings show fungal hyphae in epidermis; best yield from scrapings from active border
- Arthrospores found in hair shafts; spores and/or hyphae seen on KOH exam

TREATMENT

GENERAL MEASURES
- Careful hand washing and personal hygiene; laundering of towels/clothing of affected individual; no sharing of towels/clothes/headgear/pillows
- Evaluate other family members, close contacts, or household pets (especially kittens and puppies).
- Use of prophylactic antifungal shampoo by all household members for 2 to 4 weeks in cases of tinea capitis
- Avoid predisposing conditions such as hot baths and tight-fitting clothing (boxer shorts are better than briefs).
- Keep area as dry as possible (talcum/powders may be beneficial).
- Itching can be alleviated by OTC preparations such as Sarna or Prax.
- Topical steroid preparations should be avoided, unless absolutely needed to control itching and only after definitive diagnosis and initiation of antifungal treatment.
- Nystatin should be avoided in tinea infections but is indicated for cutaneous candidal infections.
- Avoid contact sports (e.g., wrestling) temporarily while starting treatment.

MEDICATION

First Line
- Tinea cruris/corporis (2,3)
  - Topical azole antifungal compounds
    - Terbinafine 1% (Lamisil): OTC inexpensive and effective compound; can be applied once or BID for 1 to 3 weeks
    - Econazole 1% (Spectazole), ketoconazole (Nizoral): usually applied BID for 2 to 3 weeks
    - Butenafine 1% (Mentax): applied once daily for 2 weeks; also very effective. To prevent relapse, use for 1 week after resolution.
- Tinea capitis (4)[A]
  - PO griseofulvin for Trichophyton and Microsporum sp.; microsized preparation available; dosage 10 to 20 mg/kg/day (max 1,000 mg); taken BID or as a single dose daily for 6 to 12 weeks
  - PO terbinafine can be used for Trichophyton sp. at 62.5 mg/day in patients weighing 10 to 20 kg; 125 mg/day if weight 20 to 40 kg; 250 mg/day if weight >40 kg; use for 4 to 6 weeks.
  - PO itraconazole can be used for Microsporum sp. and matches griseofulvin efficacy while
being better tolerated; dosage of 3 to 5 mg/kg/day, but most studies have used 100 mg/day for 6 weeks in children >2 years of age

Second Line
Tinea cruris/corporis
- Oral antifungal agents are effective but not indicated in uncomplicated tinea cruris/corporis cases. They can be used for resistant and extensive infections or if the patient is immunocompromised. If topical therapy fails, consider possible oral therapy. Griseofulvin can be given 500 mg/day for 1 to 2 weeks.
- The following oral regimens have been reported in medical literature as being effective but currently are not specifically approved by FDA for tinea cruris:
  - PO terbinafine (Lamisil): 250 mg/day for 1 week
  - PO itraconazole (Sporanox): 100 mg BID once and repeated 1 week later
  - PO fluconazole (Diflucan): 150 mg once per week for 4 weeks
- Topical terbinafine 1% solution has been studied recently and appears effective as a once-daily application for 1 week.
- Oral antifungals have many interactions including warfarin, OCPs, and alcohol; advise checking for drug interactions prior to use; contraindicated in pregnancy. Monitor for liver toxicity when using oral antifungals.

ISSUES FOR REFERRAL
Refer if disease is nonresponsive/resistant, especially in immunocompromised host.

ADDITIONAL THERAPIES
Treatment of secondary bacterial infections

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Reevaluate response to treatment.

Patient Monitoring
Liver function testing prior to therapy and at regular intervals during course of therapy for patients requiring oral terbinafine, fluconazole, itraconazole, and griseofulvin

PATIENT EDUCATION
Explain the causative agents, predisposing factors, and prevention measures.

PROGNOSIS
- Excellent prognosis for cure with therapy in tinea cruris and corporis
- In tinea capitis, lesions will heal spontaneously in 6 months without treatment, but scarring is more likely.

COMPLICATIONS
- Secondary bacterial infection
- Generalized, invasive dermatophyte infection
- Secondary eruptions called dermatophytid reactions (which occur in association with primary/inflammatory skin disorders) may occur at distant sites.
REFERENCES

ADDITIONAL READING

CODES

ICD10

- B35.0 Tinea barbae and tinea capitis
- B35.4 Tinea corporis
- B35.6 Tinea cruris

CLINICAL PEARLS

- Tinea corporis is characterized by scaly plaque, with peripheral activity and central clearing.
- Tinea cruris is characterized by erythematous plaque in crural folds usually sparing the scrotum. Treatment of concomitant tinea pedis is advised.
- Tinea capitis is a fungal infection of the scalp affecting hair growth. Topical therapy is ineffective for this infection.
TINEA PEDIS
Elisabeth L. Backer, MD

BASICS

DESCRIPTION
- Superficial infection of the feet caused by dermatophytes
- Most common dermatophyte infection encountered in clinical practice; contagious
- Often accompanied by tinea manuum, tinea unguium, and tinea cruris
- Clinical forms: interdigital (most common), hyperkeratotic (moccasin type), vesiculobullous (inflammatory), and rarely ulcerative
- System(s) affected: skin/exocrine
- Synonym(s): athlete’s foot

EPIDEMIOLOGY
- Predominant age: 20 to 50 years, although can occur at any age (1)
- Predominant gender: male > female

Prevalence
4% of population

Pediatric Considerations
Rare in younger children; common in adolescents

Geriatric Considerations
Elderly are more susceptible to outbreaks because of immunocompromised and impaired perfusion of distal extremities.

ETIOLOGY AND PATHOPHYSIOLOGY
Superficial infection caused by dermatophytes that thrive only in nonviable keratinized tissue
- Trichophyton interdigitale (previously Trichophyton mentagrophytes) (acute)
- Trichophyton rubrum (chronic)
- Trichophyton tonsurans
- Epidermophyton floccosum

Genetics
No known genetic pattern

RISK FACTORS
- Hot, humid weather
- Sweating
- Occlusive/tight-fitting footwear
- Immunosuppression
- Prolonged application of topical steroids

GENERAL PREVENTION
- Good personal hygiene
- Wearing rubber or wooden sandals in community showers, bathing places, locker rooms
- Careful drying between toes after showering or bathing; blow-drying feet with hair dryer may be more effective than drying with towel.
- Changing socks and shoes frequently
- Applying drying or dusting powder
- Applying topical antiperspirants
- Putting on socks before underwear to prevent infection from spreading to groin

**COMMONLY ASSOCIATED CONDITIONS**
- Hyperhidrosis
- Onychomycosis
- Tinea manuum/unguium/cruris/corporis

---

**DIAGNOSIS**

**HISTORY**
- Itchy, scaly rash on foot, usually between toes; may progress to fissuring/maceration in toe web spaces
- May be associated with onychomycosis and other tinea infections
- May be complicated by secondary bacterial infections

**PHYSICAL EXAM**
- Acute form: self-limited, intermittent, recurrent; scaling, thickening, and fissuring of sole and heel; scaling or fissuring of toe webs; or pruritic vesicular/bullous lesions between toes or on soles
- Chronic form: most common; slowly progressive, pruritic erythematous erosion/scales between toes, in digital interspaces; extension onto soles, sides/dorsum of feet (moccasin distribution); if untreated, may persist indefinitely
- Other features: strong odor, hyperkeratosis, maceration, ulceration
- Tinea pedis may occur unilateral or bilateral.
- Secondary presumably immune-mediated eruptions called dermatophytid reactions may occur at distant sites.

**DIFFERENTIAL DIAGNOSIS**
- Interdigital type: erythrasma, impetigo, pitted keratolysis, candidal intertrigo
- Moccasin type: psoriasis vulgaris, eczematous dermatitis, pitted keratolysis
- Inflammatory/bullous type: impetigo, allergic contact dermatitis, dyshidrotic eczema (negative KOH examination of scrapings), bullous disease

**DIAGNOSTIC TESTS & INTERPRETATION**
Wood lamp exam will not fluoresce unless complicated by another fungus, which is uncommon: Malassezia furfur (yellow to white), Corynebacterium (red), or Microsporum (blue green).

**Initial Tests (lab, imaging)**
- Testing is not needed in typical presentation.
- Direct microscopic exam (potassium hydroxide) of scrapings of the lesions
- Culture (Sabouraud medium)
Test Interpretation

- Potassium hydroxide preparation: septate and branched mycelia
- Culture: dermatophyte

TREATMENT

Treatment is generally with topical antifungal medications for up to 4 weeks and is more effective than placebo:

- Acute treatment
  - Aluminum acetate soak (Burow’s solution; Domeboro, 1 pack to 1 quart warm water) to decrease itching and acute eczematous reaction
  - Antifungal cream of choice BID after soaks (allylamines slightly more effective than azoles)

- Chronic treatment:
  - Antifungal creams BID, continuing for 3 days after the rash is resolved: terbinafine 1% (possibly most effective topical), clotrimazole 1%, econazole 1%, ketoconazole 2%, tolnaftate 1%, etc. (2)[A]
  - May try systemic antifungal therapy; see below (consider if concomitant onychomycosis or after failed topical treatment).

GENERAL MEASURES

- Soak with aluminum chloride 30% or aluminum subacetate for 20 minutes BID.
- Careful removal of dead/thickened skin after soaking or bathing
- Treatment of shoes with antifungal powders
- Avoidance of occlusive footwear
- Chronic or extensive disease or nail involvement requires oral antifungal medication and systemic therapy.

MEDICATION

For use when topical therapy has failed

First Line

- Systemic antifungals (3)[A]:
  - Itraconazole: 200 mg PO BID for 7 days (cure rate >90%)
  - Terbinafine: 250 mg/day PO for 14 days
- If concomitant onychomycosis:
  - Itraconazole: 200 mg PO BID for 1st week of month for 3 months. Liver function testing is recommended.
  - Terbinafine: 250 mg/day PO for 12 weeks, or pulse dosing: 500 mg/day PO for 1st week of month for 3 months; not recommended if creatinine clearance <50 mL/min
- Pediatric dosing options:
  - Griseofulvin: 10 to 15 mg/kg/day or divided
  - Terbinafine:
    - 10 to 20 kg: 62.5 mg/day
    - 20 to 40 kg: 125 mg/day
    - >40 kg: 250 mg/day
- Itraconazole: 3 to 5 mg/kg/day
Fluconazole: 6 mg/kg/week
Contraindications: itraconazole, pregnancy Category C
Precautions: All systemic antifungal drugs may have potential hepatotoxicity.
Significant possible interactions: Itraconazole requires gastric acid for absorption; effectiveness is reduced with antacids, H₂ blockers, proton pump inhibitors, etc. Take with acidic beverage, such as soda if on antacids.

**Second Line**
- Systemic antifungals: griseofulvin 250 to 500 mg of microsize BID daily for 21 days
  - Contraindications (griseofulvin):
    - Patients with porphyria, hepatocellular failure
    - Patients with history of hypersensitivity to griseofulvin
  - Precautions (griseofulvin):
    - Should be used only in severe cases
    - Periodic monitoring of organ system functioning, including renal, hepatic, and hematopoietic
    - Possible photosensitivity reactions
    - Lupus erythematosus, lupus-like syndromes, or exacerbation of existing lupus erythematosus has been reported.
- Significant possible interactions (griseofulvin):
  - Decreases activity of warfarin-type anticoagulants
  - Barbiturates usually depress griseofulvin activity.
  - May potentiate effect of alcohol, producing tachycardia and flush

**ISSUES FOR REFERRAL**
If extensive or resistant disease, especially in immunocompromised host

**ADDITIONAL THERAPIES**
- Treatment of secondary bacterial infections
- Treatment of eczematoid changes

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Avoid sweat buildup along feet.

**Patient Monitoring**
Evaluate for response, recognizing that infections may be chronic/recurrent.

**DIET**
No restrictions

**PATIENT EDUCATION**
See “General Prevention.”

**PROGNOSIS**
- Control but not complete cure
- Infections tend to be chronic with exacerbations (e.g., in hot, humid weather).
- Personal hygiene and preventive measures, such as open-toed sandals, careful drying, and frequent sock changes are essential.

**COMPLICATIONS**
- Secondary bacterial infections (common portal of entry for streptococcal infections, producing lymphangitis/cellulitis of lower extremity)
- Eczematoid changes

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**
- Dermatitis, Contact; Dyshidrosis

**CODES**

**ICD10**
- B35.3 Tinea pedis

**CLINICAL PEARLS**
- Treatment with topical antifungal medications for up to 4 weeks usually suffices.
- Tinea pedis is often recurrent or chronic in nature.
- Careful drying between toes after showering or bathing helps prevent recurrences. (Blow drying feet with hair dryer may be more effective than drying with towel.)
- Socks should be changed frequently. Put on socks before underwear to prevent infection from spreading to groin (tinea cruris).
- Dusting and desiccating powders (containing antifungal agents) may prevent recurrences.
TINEA VERSICOLOR
Arabelle Abellard, MD, MSc ● Jacqueline R. Ivey-Brown, MD, FACP

BASICS

DESCRIPTION
- Superficial fungal infection that interferes with normal skin pigmentation resulting in macules or patches that are hypopigmented, tan, brown, or salmon-colored. Tinea versicolor is usually well-demarcated, finely scaling, occurring primarily on the trunk and proximal upper extremities. Tinea versicolor is not a dermatophyte infection. It is caused by lipophilic (fat/oil-loving) Malassezia yeast organisms that normally inhabit the skin.

- System(s) affected: skin/exocrine
- Synonym(s): pityriasis versicolor

EPIDEMIOLOGY

Incidence
- Common, occurs worldwide, especially in tropical climates
- Predominant age: adolescents and young adults
- Predominant sex: male = female

Pediatric Considerations
Skin eruptions usually occur after puberty, when sebaceous glands are more active. However tinea versicolor can also be seen in children, especially in tropical climates; facial lesions are more common in children.

Geriatric Considerations
Not common in the geriatric population

Prevalence
Prevalence can reach up to 50%, especially in warm climates.

ETIOLOGY
The inhibition of pigment synthesis in epidermal melanocytes leads to hypopigmented skin patches; in the hyperpigmented type, melanosomes increase in size resulting in brown or darker skin patches of varying shades (1).

- Tinea versicolor is caused by saprophytic yeast: Pityrosporum orbiculare (also known as Plasmodium ovale, Malassezia furfur, or Malassezia ovalis), which is a known colonizer of all humans.

- Development of clinical disease is associated with transformation of Malassezia from yeast cells to pathogenic mycelial form. Several endogenous (host) and exogenous/external factors may play a role in the transformation to active disease.

- Tinea versicolor is not linked to poor hygiene.

Genetics
Genetic predisposition may exist.

**RISK FACTORS**
- Hot, humid weather
- Use of topical skin oils
- Hyperhidrosis
- HIV infection/immunosuppression
- High cortisol levels (Cushing, prolonged steroid administration)
- Pregnancy
- Malnutrition
- Oral contraceptives

**GENERAL PREVENTION**
- Prophylaxis can be used in warm summer months and prior to tanning season in people with frequent recurrences.
- Avoiding skin oils may help
- Tinea versicolor is not contagious.

**DIAGNOSIS**

**HISTORY**
- Asymptomatic scaling macules typically affect the trunk and shoulders.
- Mild pruritus may occur.
- Skin eruptions are more prominent in summer months.
- Sun tanning accentuates lesions because affected areas usually do not tan.
- Periodic recurrences are common, especially in warm, summer months and in tropical areas.

**PHYSICAL EXAM**
- Versicolor refers to the variety and changing shades of colors. Color variations can exist between individuals and also between lesions.
- Sun exposure usually makes hypopigmented, light-colored patches more noticeable.
- In covered areas, lesions are often brown or salmon-colored.
- Distribution (sebum-rich areas): mostly chest, shoulders, back (sometimes face and intertriginous areas). In children, the face is more likely to be involved.
- Appearance: Tinea versicolor usually presents as small individual macules that frequently coalesce to form patches.
- Fine scales are present over the lesions and become more visible with scraping.

**DIFFERENTIAL DIAGNOSIS**
Other skin diseases with discolored macules and plaques include the following:
- Pityriasis alba/rosea (“Christmas tree-like” distribution visible in P. rosea)
- Vitiligo (presents without scaling)
- Seborrheic dermatitis (more erythematous; thicker scale)
- Nummular eczema
- Secondary syphilis
- Erythrasma
- Mycosis fungoides
DIAGNOSTIC TESTS & INTERPRETATION
Visualization of affected skin under Wood’s light often appears fluorescent yellow to yellow-green.

Initial Tests (lab, imaging)
- Direct microscopy of scales with 10% potassium hydroxide (KOH) preparation shows hyphae and spores (“spaghetti and meatballs” pattern).
- Routine lab tests are usually not necessary.
- Fungal culture is not useful.

Test Interpretation
- Short, stubby, or Y-shaped hyphae
- Small, round spores in clusters on hyphae

TREATMENT

GENERAL MEASURES
- Apply prescribed topical medications to the affected skin.
- Pigmentation/discoloration may take months to improve.
- In people with recurrences, repeat treatment each spring prior to sun exposure may be beneficial; consider monthly prophylaxis during the summer months.
- Patients who fail topical treatment can be treated with an oral/systemic medication.

MEDICATION
Topical antifungal therapy is the treatment of choice in limited disease and is safe and usually effective. Evidence is generally of poor quality, but data suggest that longer durations of treatment and higher concentrations of active agents produce greater cure rates (2)[A].

First Line
- Ketoconazole 2% shampoo applied to damp skin and left on for 5 minutes for 1 to 3 days (Ketoconazole is contraindicated in pregnancy) or
- Ketoconazole 2% (Nizoral) cream BID for 2 to 4 weeks (Ketoconazole is contraindicated in pregnancy) or
- Selenium sulfide shampoo 2.5% (Selsun):
  – Allowed to dry for 10 minutes prior to showering: daily for 1 week or
  – Allowed to remain on body for 12 to 24 hours prior to showering: once a week for 4 weeks or
- Clotrimazole 1% topical (Lotrimin) BID for 2 to 4 weeks or
- Miconazole 2% (Micatin, Monistat) BID for 2 to 4 weeks or
- Topical ciclopirox Olamine 1% cream BID for 2 weeks or
- Terbinafine (Lamisil) 1% solution BID for 1 week or
- Terbinafine (Lamisil DermGel) once daily for 1 week
- Newer preparations: 2.25% selenium sulfide foam; ketoconazole 2% gel
- Cure rates of topical anti-yeast preparations typically 70–80%; healing continues after active treatment. Resumption of even pigmentation may take months.

Second Line
Use for extensive and recalcitrant disease (nonresponders)

- Oral fluconazole 300 mg once weekly for 2 weeks (3)[A]
- Itraconazole 200 mg/day PO for 1 week (7 days); cure rate >90% (3)[A]

Oral ketoconazole is no longer recommended by the FDA due to risks of hepatotoxicity, adrenal insufficiency, and drug–drug interactions.

- Oral terbinafine or griseofulvin is not effective.
- Pramiconazole has been studied but is not yet available for clinical use.

**ISSUES FOR REFERRAL**
- If resistant to treatment
- If extensive disease occurs in immunocompromised host

**ONGOING CARE**

- Ketoconazole 2% or selenium sulfide 2.5% shampoo can be used weekly for maintenance or monthly for prophylaxis.
- Itraconazole 400 mg once monthly (in 2 divided dosages) during the warmer months of the year can also reduce recurrences.

**FOLLOW-UP RECOMMENDATIONS**
Inform patients that pigment changes/variations may remain for several months after treatment.

**Patient Monitoring**
- Prophylactic medication can be used in warm summer months and prior to tanning season in people with frequent recurrences.
- Failure to respond should prompt reassessment or dermatology referral.
- Resistance to treatment, frequent recurrences, or widespread disease may point to immunodeficiency.

**DIET**
There is no proven diet to treat and prevent recurrence of tinea versicolor

**PATIENT EDUCATION**
For patient education materials on this topic, contact American Academy of Dermatology, 930 N. Meacham Road, P.O. Box 4014, Schaumberg, IL 60168-4014; (708) 330-0230.

**PROGNOSIS**
- Lesions may last for months to years
- Lesions may recur periodically because Malassezia yeast organisms are known human colonizers and natural inhabitants of the skin
- Pigment changes/variations may take months to resolve.

**REFERENCES**

ADDITIONAL READING

CODES

ICD10
B36.0 Pityriasis versicolor

CLINICAL PEARLS

- Tinea versicolor is characterized by noncontagious macules of varying colors, with fine scale.
- Recurrence is common in summer months.
- Lesions tend to become more apparent after tanning. Skin areas with fungal infection do not tan; thus, hypopigmented areas become more visible.
- Inform patients that discoloration/pigment variations may remain for several months after treatment.
TINNITUS
Donna I. Meltzer, MD

BASICS
DESCRIPTION
● Tinnitus is a perceived sensation of sound in the absence of an external acoustic stimulus often described as a ringing, hissing, buzzing, or whooshing.
● Derived from the Latin word tinnire, meaning “to ring”
● May be heard in one or both ears or centrally within the head
● Two types: subjective (most common) and objective tinnitus
  – Subjective tinnitus: perceived only by the patient; can be continuous, intermittent, or pulsatile
  – Objective tinnitus: audible to the examiner; usually pulsatile; <1% cases (1)
● Primary tinnitus: idiopathic with or without sensorineural hearing loss (SNHL) (2)
● Secondary tinnitus: associated with a specific cause (other than SNHL)

EPIDEMIOLOGY
Incidence
● Incidence increasing in association with excessive noise exposure
● Higher rates of tinnitus in smokers, hypertensives, diabetics, and obese patients

Prevalence
● Tinnitus reported by 35 to 50 million adults in United States; although underreported, 12 million seek medical care.
● Affects 10–15% of adults
● Prevalence increases with age and peaks in 6th decade.
● Prevalence of 13–53% in general pediatric population
● Ethnic: whites > blacks and Hispanics
● Gender: males > females

ETIOLOGY AND PATHOPHYSIOLOGY
● Precise pathophysiology is unknown; numerous theories have been proposed. Cochlear damage from ototoxic agents or noise exposure damages hair cells so that the central auditory system compensates, resulting in hyperactivity in cochlear nucleus and auditory cortex.
● Causes of subjective tinnitus:
  – Otologic: hearing loss, cholesteatoma, cerumen impaction, otosclerosis, Ménière disease, vestibular schwannoma
  – Ototoxic medications: anti-inflammatory agents (aspirin, NSAIDs); antimalarial agents, antimicrobial drugs (aminoglycosides); antineoplastic agents, loop diuretics, miscellaneous drugs (antiarrhythmics, antiulcer, anticonvulsants, antihypertensives); psychotropic drugs; anesthetics (1)
  – Somatic: temporomandibular joint (TMJ) dysfunction, head or neck injury
  – Neurologic: multiple sclerosis, spontaneous intracranial hypertension, vestibular migraine, type I Chiari malformation
  – Infectious: viral, bacterial, fungal
- Causes of objective tinnitus:
  - Vascular: aortic or carotid stenosis, venous hum, arteriovenous fistula or malformation, vascular tumors, high cardiac output state (anemia)
  - Neurologic: palatal myoclonus, idiopathic stapedial muscle spasm
  - Patulous eustachian tube

**Genetics**
Minimal genetic component

**RISK FACTORS**
- Hearing loss (but can have tinnitus with normal hearing)
- High-level noise exposure
- Advanced age
- Use of ototoxic medications
- Otologic disease (otosclerosis, Ménière disease, cerumen impaction)
- Depression and anxiety associated with increased odds of tinnitus

**GENERAL PREVENTION**
- Avoid loud noise exposure and wear appropriate ear protection to prevent hearing loss.
- Monitor ototoxic medications and avoid prescribing more than one ototoxic agent concurrently.

**COMMONLY ASSOCIATED CONDITIONS**
- SNHL caused by presbycusis (age-associated hearing loss) or prolonged loud noise exposure
- Conductive hearing loss due to cerumen, otosclerosis, cholesteatoma
- Psychological disorders: depression, anxiety, insomnia, suicidal ideation
- Despair, frustration, interference with concentration and social interactions, work hindrance

**DIAGNOSIS**

**HISTORY**
- Onset gradual (presbycusis) or abrupt (following loud noise exposure)
- Timing: can be continuous (hearing loss) or intermittent (Ménière disease)
- Pattern: nonpulsatile > pulsatile (often vascular cause)
- Location: bilateral > unilateral (vestibular schwannoma, cerumen, Ménière disease)
- Pitch: high pitch (with SNHL) > low pitch (Ménière disease)
- Associated symptoms: hearing loss, headache, noise intolerance, vertigo, TMJ dysfunction, neck pain
- Exacerbating factors: loud noise; jaw, head, or neck movements
- Alleviating factors: hearing aid, position change, medications
- Medication use (prescription, OTC, supplements)
- Hearing and past noise exposure (occupational, military, recreational)
- Psychosocial history (depression, sleep habits)
- Impact of tinnitus: Tinnitus Handicap Inventory, Tinnitus Functional Index

**PHYSICAL EXAM**
- HEENT, neck, neurologic, and vascular examinations
Ear: cerumen impaction, effusion, cholesteatoma
Check hearing; air and bone conduction testing with 512- or 1,024-Hz tuning fork (Weber and Rinne tests)
Eye: funduscopic exam for papilledema (intracranial hypertension) or visual field change (mass)
TMJ: Palpate for tenderness and crepitus with movement.
Crani al nerve, Romberg test (equilibrium), finger to nose, gait; assess for nystagmus.
Auscultate for bruits or murmurs; compress jugular vein (suspect venous etiology if maneuver reduces tinnitus)

DIFFERENTIAL DIAGNOSIS
Pulsatile tinnitus: carotid stenosis, aortic valve disease, AV malformation, high cardiac output state (anemia, hyperthyroidism), paraganglioma (glomus tumor)
Nonpulsatile tinnitus: auditory hallucinations

DIAGNOSTIC TESTS & INTERPRETATION
Tinnitus is a symptom; no objective test to confirm diagnosis
Pure tone audiometry (air and bone conduction)
Speech discrimination testing
Tympanometry
Carotid Doppler ultrasonography (neck bruit)

Initial Tests (lab, imaging)
Little evidence to support lab testing other than targeted lab studies based on history and physical exam. Use clinical judgment and consider the following:
– CBC
– BUN/creatinine, fasting glucose, lipid panel
– Thyroid-stimulating hormone
Newer guidelines advise against imaging studies unless have unilateral, pulsatile tinnitus; focal neurologic abnormality; or asymmetric hearing loss (2)[C].
CT of temporal bone is initial imaging study of middle ear, especially if conductive hearing loss
Pulsatile tinnitus: temporal bone CT, CTA/CTV with contrast, MRA without or with contrast, or MRI head and internal auditory canal (IAC) without and with contrast are usually appropriate (3)[C]; could also consider carotid duplex or Doppler ultrasound
Unilateral nonpulsatile tinnitus: MRI head and IAC without and with contrast; might consider CT temporal bone without and with contrast or CTA with contrast (3)[C]
Bilateral nonpulsatile tinnitus: imaging not indicated if no hearing loss, neurologic deficit, or trauma (3)[C]

Follow-Up Tests & Special Considerations
Consider HIV, RPR, autoimmune panel, Lyme test, vitamin B_{12} level.

Diagnostic Procedures/Other
Electronystagmography (vestibular testing for Ménière disease)
TREATMENT

GENERAL MEASURES
- Individualize treatment based on the severity of tinnitus and impact on function.
- Reassure patient.
- Manage treatable pathology.
- Education, relaxation therapy, cognitive-behavioral therapy (CBT)
- Hearing aids (corrects hearing and might mask tinnitus) can be tried if there is hearing loss and bothersome tinnitus (2)[C]
- Protect hearing against future loud noise.
- Masking sound devices or generators on discontinuation might have decreased tinnitus (residual inhibition).
- Discontinue ototoxic medications.

MEDICATION
No pharmacologic agent has been shown to cure or consistently alleviate tinnitus.

First Line
- Antidepressants (SSRIs or TCAs): probably help with psychological distress; insufficient evidence that antidepressant drug therapy improves tinnitus (4)[A]
- Melatonin decreases tinnitus intensity and improves sleep quality; most effective in men, those without depression or prior treatment, and those with more severe bilateral tinnitus (5)[B]

Second Line
- Anticonvulsants: potentially suppress central auditory hyperactivity but not recommended (2)[C]
- Insufficient evidence to recommend gabapentin (6)[B]
- Higher caffeine intake associated with lower incidence of tinnitus in women (7)[B]

ISSUES FOR REFERRAL
- Audiologist for comprehensive hearing evaluation and management
- Otolaryngologist, neurologist, or neurosurgeon depending on pathology
- Dental referral for TMJ treatment and dental orthotics (splint, night guard)
- Therapists for CBT, biofeedback, education, and relaxation techniques

ADDITIONAL THERAPIES
- Sound therapy (masking): Patients wear low-level noise generators to mask the tinnitus noise; optional therapy (2)[C]
- CBT employs relaxation exercises, coping strategies, and deconditioning techniques to reduce arousal levels and reverse negative thoughts about tinnitus; recommended as beneficial based on randomized controlled trials (2)[C]
- Tinnitus retraining therapy (TRT) combines counseling, education, and acoustic therapy (soft music, sound machine) to minimize bothersome nature of tinnitus; often requires a team approach and up to 2 years of therapy; might be more effective than sound masking (8)[B]
- Transcranial magnetic stimulation (TMS): a noninvasive method to stimulate neurons in the brain by rapidly changing magnetic fields; not recommended as randomized trials were inconclusive (2)[C]
Botulism toxin (for palatal myoclonus)
Intratympanic steroid injections not recommended (2)[C]
Hyperbaric oxygen: no beneficial effect on tinnitus
Cannabis: not enough evidence to recommend

SURGERY/OTHER PROCEDURES
- Cochlear implants (for severe SNHL)
- Ablation of cochlear nerve (destroys hearing)
- Epidural stimulation of secondary auditory cortex with implanted electrodes suppressed tinnitus in small subset of patients.
- Otosclerosis: stapedectomy surgery with implantation of ossicular prosthesis
- Severe Ménière disease not alleviated by medications: installation of endolymphatic shunt, labyrinthectomy, or vestibular neurectomy
- Auditory neoplasms: surgical resection/radiation
- Pulsatile tinnitus due to atherosclerotic carotid artery disease: carotid endarterectomy

COMPLEMENTARY & ALTERNATIVE MEDICINE
- One evidence-based practice guideline does not recommend ginkgo biloba, melatonin, zinc, or other dietary supplements for treatment of persistent, bothersome tinnitus (2)[C].
- Hypnosis (unknown effectiveness)
- Acupuncture therapy may offer subjective benefits to some patients (9)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Not applicable

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Audiologist: for hearing evaluation and therapy
- Counseling as needed for psychological distress
- Family physician: as needed for support and guidance

PATIENT EDUCATION
- American Tinnitus Association: (800) 634-8978; https://www.ata.org/
- National Institute on Deafness and Other Communication Disorders: (800) 241-1044; https://www.nidcd.nih.gov/health/tinnitus

PROGNOSIS
- Tinnitus persisted in 80% of older patients and increased in severity in 50% (1).
- Focus on managing tinnitus and reducing severity, not curing.

REFERENCES

CODES

ICD10
- H93.19 Tinnitus, unspecified ear
- H93.11 Tinnitus, right ear
- H93.12 Tinnitus, left ear

CLINICAL PEARLS

- People have different levels of tolerance to tinnitus. It may affect sleep, concentration, and emotional state. Many patients with chronic tinnitus have depression.
- To keep tinnitus from worsening, avoid loud noises and minimize stress.
- Optimal management may involve multiple strategies.
TOBACCO USE AND SMOKING CESSATION
Felix B. Chang Cruz, MD, FAAMA, ABIHM • Roberto S. Amado, MD

BASICS
Use of tobacco of any form

DESCRIPTION
• The second leading actual cause of death in the United States
• Smokeless tobacco refers to tobacco products that are vaporized, sniffed, sucked, or chewed.
• Nicotine sources: cigars, pipes, water pipes, hookahs, cigarettes, and electronic cigarettes
• Electronic nicotine delivery system (ENDS) use is on the rise.
• History of using e-cigarette, or vaping, products

EPIDEMIOLOGY
The Centers for Disease Control (CDC) reported that there are 1,080 cases of lung illness reported from 48 states and 1 U.S territory related to vaping and/or e-cigarette use. Eighteen deaths have been confirmed in 15 states.

Incidence
• 2.4 million new smokers annually in the United States (2.6% initiation rate)
• 59% of new smokers are <18 years of age (5.8% initiation rate for teens).
• 9.7 million people age >18 years smoke 20 or more cigarettes daily.

Prevalence
• 14% of all adults (34.3 million people): 15.8% of males, 12.2% of females are current cigarette smokers.
• Age: highest among those ages 45 to 64 years (16.5%)
• Race: highest among Native Americans (24.0%) and lower among Hispanics (9.9%) and Asians (7.1%)
• Gender: male > female (15.8% vs. 12.2%)
• Education: inversely proportional to education level
• Psychological association: nearly 36% of adults with a serious psychological distress compared to 14% without this distress
• Cigarette smoking is responsible for >480,000 deaths per year in the United States, including >41,000 deaths from secondhand smoke exposure. This is about 1 in 5 deaths annually or 1,300 deaths every day.
• Overall, in 2016, 15.3% of adults had ever used an e-cigarette, 3.2% were current users.
• The prevalence of current e-cigarette use was highest in current cigarette smokers 10.8%, followed by former smokers 4.8%.
• In 2018, 21% of high school students reported current use of e-cigarettes, up from 12 percent in 2017.
• 5% of middle school students reported current e-cigarette use.
• Approximately 80% of patients are under 35 years old. 16% of patients are under 18 years old, 21% of patients are 18 to 20 years old.
ETIOLOGY AND PATHOPHYSIOLOGY

- Addiction due to nicotine’s rapid stimulation of the brain’s dopamine system (teenage brain especially susceptible)
- Atherosclerotic risk due to adrenergic stimulation, endothelial damage, carbon monoxide, and adverse effects on lipids
- Direct airway damage from cigarette tar
- Carcinogens in all tobacco products
- E-cigarettes range from nicotine free up to 36 mg/ml.
- Potential adverse effects of e-cigarettes are related to exposure to nicotine as well as to other vapor components produced by the devices and risk of actual device.
- If e-cigarette, or vaping product use is suspected as a possible etiology of a patient’s lung injury, obtain detailed history regarding:
  - Substance(s) used: nicotine, cannabinoids (e.g., marijuana, THC, THC concentrates, CBD, CBD oil, synthetic cannabinoids [e.g., K2 or spice], hash oil, Dank vapes), flavors, or other substances
  - Substance source(s): commercially available liquids (i.e., bottles, cartridges, or pods), homemade liquids, and re-use of old cartridges or pods with homemade or commercially bought liquids
  - Device(s) used: manufacturer; brand name; product name; model; serial number of the product, device, or e-liquid; product/device customization or modification by the user (e.g., exposure of the atomizer or heating coil)

RISK FACTORS

- Presence of a smoker in the household
- Easy access to cigarettes
- Comorbid stress and psychiatric disorders
- Low self-esteem/self-worth
- Poor academic performance
- Boys: high levels of aggression and rebelliousness
- Girls: preoccupation with weight and body image
- Electronic cigarette use has been associated with several cases of idiopathic acute eosinophilic pneumonia
- Lipoid pneumonia associated with inhalation of lipids in aerosols generated by e-cigarettes has been reported.

GENERAL PREVENTION

- Most first-time tobacco use occurs before high school graduation.
- The Tar Wars program of the American Academy of Family Physicians has successfully targeted tobacco use prevention in 4th and 5th graders.
- Smoking bans in public areas and workplaces
- Restriction of minors’ access to tobacco
- Restrictions on tobacco advertisements
- Raising prices through taxation
- Media literacy education
- Tobacco-free sports initiatives

COMMONLY ASSOCIATED CONDITIONS
Coronary artery disease
Cerebrovascular disease
Peripheral vascular disease
Abdominal aortic aneurysm (AAA)
Chronic obstructive coronary disease (COPD)
Cancer of the lip, oral cavity, pharynx, larynx, lung, esophagus, stomach, pancreas, kidney, urinary bladder, cervix, and blood
Pneumonia, osteoporosis
Periodontitis
Alcohol use
Depression and anxiety
Reduced fertility
Vaping/e-cigarette use has been associated with cough, shortness of breath, fatigue, fever, chest pain, weight loss, nausea, and diarrhea.

Pregnancy Considerations
Women who smoke or are exposed to secondhand smoke during pregnancy have increased risks of miscarriage, placenta previa, placental abruption, premature rupture of membranes, preterm delivery, low-birth-weight infants, and stillbirth.

Pediatric Considerations
- Secondhand smoke increases the risk for:
  - Sudden infant death syndrome
  - Acute upper and lower respiratory tract infections
  - More severe exacerbations of asthma
  - Otitis media and need for tympanostomies
- Nicotine passes through breast milk. Effects on growth and development of nursing infants are unknown.

DIAGNOSIS

HISTORY
- Ask about tobacco use and secondhand smoke exposure at every physician encounter.
- Type and quantity of tobacco used:
  - “Heavy smoking” is 20 or more cigarettes per day or 20 or more pack-years.
  - Pack-years = packs/day × years. Twenty pack-years is equivalent to a pack a day for 20 years or 2 packs a day for 10 years. Other common cut points for heavy smoking include 15 and 25 cigarettes per day.
- Assess for awareness of health risks.
- Assess interest in quitting.
- Identify triggers for smoking: stress, habit, pleasure.
- Prior attempts to quit: method, duration of success, reason for relapse

PHYSICAL EXAM
- General: tobacco smoke odor, staining of facial hair
- Skin: premature wrinkling, especially the face
- Mouth: nicotine-stained teeth; inspect for mucosal changes, hypertrophy, fungating lesions.
Lungs: crackles, wheezing, increased or decreased volume, chronic cough
Vessels: carotid or abdominal bruits, abdominal aortic enlargement or aneurysm, weak peripheral pulses, stigmata of peripheral vascular disease

**DIAGNOSTIC TESTS & INTERPRETATION**
- Chest x-ray for patients with pulmonary symptoms or signs of cancer but not for screening
- The U.S. Preventive Services Task Force (USPSTF) recommends one-time screening abdominal ultrasound (US) for AAA in men ≥65 years of age who ever smoked (number needed to screen to prevent one AAA = 500).
- Low-dose computed tomography is more sensitive than chest radiograph for identifying small, asymptomatic lung cancers.
- USPSTF recommends yearly screening for lung cancer with low-dose CT for individuals 55 to 80 years with a 30 pack-years history of smoking; current smokers or those who have quit within past 15 years

**Diagnostic Procedures/Other**
Pulmonary function tests for smokers with chronic pulmonary symptoms, such as wheezing, cough, or dyspnea. This includes spirometry, diffusion studies, and body plethysmography.

**TREATMENT**
Both behavioral counseling and pharmacotherapy benefit patients who are trying to quit smoking especially when used in combination.

**ALERT**
Report cases of lung injury of unclear etiology and a history of e-cigarette or vaping product use within the past 90 days to state or local health department. Ask all patients who report e-cigarette or vaping product use within the last 90 days about signs and symptoms of respiratory illness.

**GENERAL MEASURES**
- Behavioral counseling includes the 5 As:
  - Ask about tobacco use at every office visit.
  - Advise all smokers to quit.
  - Assess the patient’s willingness to quit.
  - Assist the patient in his or her attempt to quit and provide quit line number (1-800-QUIT-NOW in the United States).
  - Arrange follow-up and support.
- Patients ready to quit smoking should set a quit date within the next 2 weeks; no difference in success rates between patients who taper prior to their quit date and those who stop abruptly
- Success increased with a quitting partner, such as a spouse, friend, or coworker, to provide mutual encouragement.

**MEDICATION**
**First Line**
- Varenicline (Chantix): 0.5 mg/day PO for 3 days, then 0.5 mg BID for 4 days, and then 1 mg BID for 11 weeks ([A]:
  - Start 1 to 4 weeks prior to smoking cessation and continue for 12 to 24 weeks.
– Superior versus placebo and bupropion; number needed to treat = 6 and 15, respectively
– May be combined with nicotine replacement therapy (NRT) for those with cravings
– Side effects: nausea, insomnia, headache, depression, suicidal ideation; safety not established in adolescents or patients with psychiatric or cardiovascular disease; pregnancy Category C

– Bupropion SR (Zyban): 150 mg PO for 3 days and then 150 mg BID:
  – Start 1 week prior to smoking cessation and continue for 7 to 12 weeks.
  – Twice as effective as placebo
  – Drug of choice for patients with depression or schizophrenia; additional benefit of weight loss
  – May be combined with varenicline and NRT in men who smoke >1 PPD

– NRT (e.g., patch, gum, lozenge, inhaler, nasal spray) (1)[A]:
  – Improves quit rates by 50–70% versus placebo
  – Available over the counter
  – Patch (NicoDerm CQ 21, 14, and 7 mg):
    o 1 patch q24h
    o Start with 21 mg if smoking ≥10 cigarettes per day; otherwise, start with 14 mg.
    o 6 weeks on initial dose and then taper
    o 2 weeks each on subsequent doses
    o No proven benefit beyond 8 weeks
  – ENDS—electronic nicotine delivery systems
    o Contain less nicotine than cigarette
    o Controversial if less “dangerous” than tobacco; not well studied as NRT
    o Conflicting data on whether teen use increases or decreases risk to cigarette progression
    o Not an effective adjunct for cessation
  – Gum (Nicorette, 2 and 4 mg):
    o Use 4 mg if smoking ≥25 cigarettes per day.
    o Chew 1 piece q1–2h for 6 weeks, then 1 piece q2–4h for 3 weeks, and then 1 piece q4–8h for 3 weeks.
  – May use in combination with bupropion; monitor for hypertension.
  – Side effects: headache, pharyngitis, cough, rhinitis, dyspepsia; all mainly with inhaler and spray forms
  – Pregnancy Category D
  – NRT is reasonable in hospitalized smokers because NRT products immediately treat nicotine withdrawal symptoms, whereas varenicline and bupropion take time to reach steady state.

**Second Line**

– Nortriptyline: 25 to 75 mg/day PO or in divided doses (1)[A]:
  – Start 10 to 14 days prior to smoking cessation and continue for at least 12 weeks.
  – Efficacy similar to bupropion, but side effects are more common; pregnancy Category D
  – The antidepressants bupropion and nortriptyline aid long-term smoking cessation (2)[A].

– Clonidine: 0.1 mg PO BID or 0.1 mg/day transdermal patch weekly (1):
  – Side effects: hypotension, bradycardia, depression, fatigue; pregnancy Category C
ADDITIONAL THERAPIES
- Electronic cigarettes: low grade of evidence
- Pharmacotherapy and behavior support increase success compared with minimal intervention or usual care (2)[A].
- Naltrexone: no evidence
- Individual behavioral counseling for smoking cessation increases effectiveness for both those with pharmacotherapy and without pharmacotherapy.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Acupuncture, aversive therapy, and hypnosis have not been proven to enhance long-term smoking cessation.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Intense counseling interventions in hospitalized patients combined with hospital follow-up for more than 1 month after discharge showed significant improvement in smoking cessation rates at 6 months or more post discharge.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Follow up 3 to 7 days after scheduled quit date and at least monthly for 3 months thereafter.
- Refraining from tobacco products for first 2 weeks is critical to long-term abstinence.
- Encourage patients who relapse to try again.
- E-cigarettes and vaping increasingly related to significant lung disease. This is an area of rapid health policy change.

Patient Monitoring
- Short-term withdrawal symptoms include dysphoria, depressed mood, irritability, anxiety, insomnia, increased appetite, and poor concentration.
- Longer term risks of smoking cessation include weight gain (4 to 5 kg on average) and depression.
- Quitting is also associated with exacerbations of ulcerative colitis and worsening of cognitive function in patients with schizophrenia.
- Nicotine withdrawal syndrome: dysphoric or depressed mood, insomnia, irritability, frustration, or anger; anxiety, difficulty concentrating, restlessness, and increased appetite or weight gain
- Lung cancer risk by smoking status: heavy smokers 1.00, light smokers 9.44 (0.35 to 0.56), ex-smokers 0.17 (0.13 to 0.23), never smoker 0.09 (0.06 to 0.13); adjusted hazard ratio (95% CI)

PATIENT EDUCATION
- 1-800-QUIT-NOW
- Affordable Care Act on impact on coverage for smoking cessation treatments: https://www.lung.org/our-initiatives/tobacco/cessation-and-prevention/affordable-care-act-tobacco.html

PROGNOSIS
- Measurable cardiovascular benefits of smoking cessation begin as early as 24 hours after
quitting and continue to mount until the risk is reduced to that of nonsmokers by 5 to 15 years.

- People who quit smoking after a heart attack or cardiac surgery reduce their risk of death by 1/3.
- Relapse rates initially >60% but decrease to 2–4% per year after completing 2 years of abstinence
- >16 million Americans are living with a disease caused by smoking or exposure to tobacco smoke.
- For every smoking-related death, at least another 30 people live with a serious smoking-related illness.
- Smokers die of 10 years earlier than nonsmokers.
- Pharmacotherapy for preoperative smokers increases cessation rates and decreases postoperative complications.

COMPLICATIONS

- Disability and premature death due to heart attack, stroke, cancer, COPD
- Smoking more than doubles the risk of coronary artery disease and doubles the risk of stroke.
- Worldwide, tobacco use causes nearly 6 million deaths per year, and current trends show that tobacco use will cause >8 million deaths annually by 2030.
- Screening by low-dose CT include complications associated with needle biopsy, bronchoscopy, and thoracotomy from false positives.

REFERENCES

SEE ALSO

Nicotine Addiction; Substance Use Disorders

CODES

ICD10

- F17.210 Nicotine dependence, cigarettes, uncomplicated
- F17.213 Nicotine dependence, cigarettes, with withdrawal
- F17.211 Nicotine dependence, cigarettes, in remission

CLINICAL PEARLS

- Every patient who uses tobacco should be offered cessation advice.
- Depression with suicidal ideations is no longer a contraindication to varenicline use; FDA
- Refrain from using e-cigarettes and vaping products.
- Nicotine replacement (delivered by nicotine polacrilex gum, nicotine lozenges, nicotine nasal spray, and transdermal nicotine) has an effect comparable to cigarette smoking in terms of
increasing myocardial work and endothelial damage. The risks associated with NRT in patients with cardiac disease, however, are lower than the risks of ongoing smoking.

- Electronic nicotine delivery systems (ENDS) are not an effective adjunct for tobacco cessation.
TOURETTE SYNDROME
Ravin V. Patel, MD • Dustin Creech, MD

BASICS

DESCRIPTION
Tourette syndrome (TS) is a movement disorder most commonly seen in school-age children; a childhood-onset neurobehavioral disorder characterized by the presence of multiple motor and at least one phonic tic (see “Physical Exam”)

- Tics are sudden, brief, repetitive, stereotyped motor movements (motor tics) or sounds (phonic tics) produced by moving air through the nose, mouth, or throat.
- Tics tend to occur in bouts.
- Tics can be simple or complex.
  - Motor tics precede vocal tics.
  - Simple tics precede complex tics.
- Tics often are preceded by sensory symptoms, especially a compulsion to move.
- Patients are able to suppress their tics, but voluntary suppression is associated with an inner tension that results in more forceful tics when suppression ceases.
- System(s) affected: nervous

EPIDEMIOLOGY

Incidence
- The onset occurs before 18 years of age.
- Predominant age
  - Average age of onset: 7 years (3 to 8 years)
  - Tic severity is greatest at ages 7 to 12 years.
    - 96% present by age 11 years
  - Of children with TS, 50% will experience complete resolution of symptoms by age 18 years (based on self-reporting).
- Predominant sex: male > female (3:1)
- Predominant race/ethnicity: clinically heterogeneous disorder, but non-Hispanic whites (2:1) compared with Hispanics and/or blacks

Prevalence
0.77% overall in children
- 1.06% in boys
- 0.25% in girls

ETIOLOGY AND PATHOPHYSIOLOGY
Abnormalities of dopamine neurotransmission and receptor hypersensitivity, most likely in the ventral striatum, play a primary role in the pathophysiology.

- Abnormality of basal ganglia development
- Thought to result from a complex interaction between social, environmental, and multiple genetic abnormalities
- Mechanism is uncertain; may involve dysfunction of basal ganglia–thalamocortical circuits, likely involving decreased inhibitory output from the basal ganglia, which results in an
imbalance of inhibition and excitation in the motor cortex

- Controversial pediatric autoimmune neuropsychiatric disorder associated with streptococcal infection (PANDAS)
  - TS/OCD cases linked to immunologic response to previous group A β-hemolytic Streptococcus (GABHS)
  - Thought to be linked to 10% of all TS cases
  - Five criteria
    - Presence of tic disorder and/or OCD
    - Prepubertal onset of neuropsychosis
    - History of sudden onset of symptoms and/or episodic course with abrupt symptom exacerbation, interspersed with periods of partial/complete remission
    - Evidence of a temporal association between onset/exacerbation of symptoms and a prior streptococcal infection
    - Adventitious movements during symptom exacerbation (e.g., motor hyperactivity)

Genetics
- Predisposition: frequent familial history of tic disorders and OCD
- Precise pattern of transmission and genetic origin unknown. Recent studies suggest polygenic inheritance with evidence for a locus on chromosome 17q; sequence variants in SLITRK1 gene on chromosome 13q also are associated with TS.
- Higher concordance in monozygotic compared with dizygotic twins; wide range of phenotypes

RISK FACTORS
- Risk of TS among relatives: 9.8–15%
- First-degree relatives of individuals with TS have a 10- to 100-fold increased risk of developing TS.
- Low birth weight, maternal stress during pregnancy, severe nausea and vomiting in 1st trimester

COMMONLY ASSOCIATED CONDITIONS
- OCD (28–67%)
- ADHD (50–60%)
- Conduct disorder
- Depression/anxiety including phobias, panic attacks, and stuttering
- Learning disabilities (23%)
- Impairments of visual perception, sleep disorders, restless leg syndrome, and migraine headaches

DIAGNOSIS

HISTORY
Diagnosis of TS is based on history and clinical presentation (i.e., observation of tics with/without presence of coexisting disorders). Identify comorbid conditions.

PHYSICAL EXAM
- Typically, the physical exam is normal.
- Motor and vocal tics are the clinical hallmarks.
Tics fluctuate in type, frequency, and anatomic distribution over time. Multiple motor tics include facial grimacing, blinking, head/neck jerking, tongue protruding, sniffing, touching, and burping. Vocal tics include grunts, snorts, throat clearing, barking, yelling, hiccupping, sucking, and coughing. Tics are exacerbated by anticipation, emotional upset, anxiety, or fatigue. Tics subside when patient is concentrating/absorbed in activities. Motor and vocal tics may persist during all stages of sleep, especially light sleep. Blink-reflex abnormalities may be observed. No known clinical measures reliably predict children who will continue to express tics in adulthood; severity of tics in late childhood is associated with future tic severity. Diagnostic and Statistical Manual of Mental Disorders (5th ed.; DSM-5) criteria (1)[C]:
- A. Both multiple motor and one or more vocal tics have been present at some time during the illness, although not necessarily concurrently.
- B. The tics may wax and wane in frequency but have persisted for >1 year since first tic onset.
- C. Onset is before age 18 years.
- D. The disturbance is not attributable to the physiologic effects of a substance (e.g., cocaine) or another medical condition (e.g., Huntington disease, postviral encephalitis).

DIFFERENTIAL DIAGNOSIS
- Chorea/Huntington disease
- Myoclonus
- Seizure
- Ischemic or hemorrhagic stroke
- Essential tremor
- Posttraumatic/head injury
- Headache
- Dementia
- Wilson disease
- Sydenham chorea
- Multiple sclerosis
- Postviral encephalitis
- Toxin exposure (e.g., carbon monoxide, cocaine)
- Drug effects (e.g., dopamine agonists, fluoroquinolones)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- No definitive lab tests diagnose TS; based on clinical features, particularly the presence of multiple motor and vocal tics
- Thyroid-stimulating hormone (TSH) should be measured because of association of tics with hyperthyroidism.
- No imaging studies diagnose TS.
- EEG shows nonspecific abnormalities; useful only to differentiate tics from epilepsy

Test Interpretation
- Smaller caudate volumes in patients with TS
TREATMENT

GENERAL MEASURES

- Many patients require no treatment; patient should play an active role in treatment decisions.
- Treatment assessment
  - Yale Global Tic Severity Scale
  - Tourette Syndrome Severity Scale
  - Global Assessment of Functioning Scale
  - Gilles de la Tourette Syndrome-Quality of Life Scale
- A detailed history is crucial to management because tics and comorbidities are interrelated. Goal of treatment should be to improve social functioning, self-esteem, and quality of life.
- Educate that tics are neither voluntary nor psychiatric.
- Educate patient, family, teachers, and friends to identify and address psychosocial stressors and environmental triggers.
- No cure for tics: Treatment is purely symptomatic, and multimodal treatment usually is indicated.
- Neurologic and psychiatric evaluation may be useful for other primary disorders and comorbid conditions (especially ADHD, OCD, and depression).
- TS clusters with several comorbid conditions; each disorder must be evaluated for associated functional impairment because patients often are more disabled by their psychiatric conditions than by the tics; choice of initial treatment depends largely on worst symptoms (tics, obsessions, or impulsivity).
- Nonpharmacologic therapy—reassurance and environmental modification, identification and treatment of trigger, and cognitive-behavioral therapy
- When pharmacotherapy is employed, monotherapy is preferred to polytherapy.

MEDICATION

First Line

- Atypical antipsychotics
  - Risperidone: now recommended for standard therapy (2)[A]
    - Initiate 0.25 mg BID; titrate to 0.25 to 6.00 mg/day.
    - As effective as haloperidol and pimozide for tics with fewer side effects
    - Effective against comorbidities such as OCD
    - Side effects may limit use: sedation, weight gain, and fatigue.
- $\alpha_2$-Adrenergic receptor agonists (2)[B]
  - Historically first-line agents due to favorable side-effect profile, but suboptimal efficacy in limited clinical trials
  - Side effects: sedation and hypotension common
    - Initiate therapy gradually and taper when discontinuing to avoid cardiac adverse events.
  - Clonidine 0.1 to 0.3 mg/day given BID–TID
    - Maximum dose: 0.5 mg/day
    - 25–50% of patients report at least some reduction in tics.
– Guanfacine 1 to 3 mg/day given daily or BID
  o Less sedating and longer duration of action compared with clonidine
  o Improves motor/vocal tics by 30% in some studies; no better than placebo in others

Second Line

● Neuroleptics
  – Typical antipsychotics
    o High risk for extrapyramidal symptoms (EPS)
      o Haloperidol: Initiate 0.5 mg/day and titrate 0.5 mg/week up to 1 to 4 mg at bedtime (3) [B].
        ■ FDA-approved for treating tics
        ■ Considered last option of typical antipsychotics due to lower efficacy and increased side effects compared to similar medications
      o Pimozide: Initiate 0.5 mg/day and titrate 0.5 mg/week up to 1 to 4 mg at bedtime (4)[A].
        ■ FDA-approved for treating tics
        ■ Risk of cardiac toxicity (prolonged QT interval and arrhythmias); must be given under ECG monitoring; long-term use may induce sedation, weight gain, depression, pseudoparkinsonism, and akathisia.
        ■ Found to work better in long-term control of tics versus acute exacerbations
    – Atypical antipsychotics (3)[C]
      o Olanzapine: Initiate 2.5 to 5.0 mg/day; titrate up to 20 mg/day.
        ■ Equally effective as haloperidol and pimozide
        ■ May cause metabolic disturbances and weight gain
      o Quetiapine: Initiate 100 to 150 mg/day; titrate to 100 to 600 mg/day.
        ■ Well tolerated, but limited data exists
      o Ziprasidone: 5 to 40 mg/day
      o Aripiprazole: Initiate 2 mg/day; titrate up to 20 or 30 mg/day.
        ■ Few studies but favorable side-effect profile

● Alternative treatments
  – Topiramate: 25 to 200 mg/day (2)[A]; promising data but not sufficient efficacy so far to recommend as first or second line
  – Tetrabenazine
  – Baclofen

● Treatment of ADHD in patients with tics (5)[A]
  – Stimulants
    o Comorbid tic disorder is not a serious contraindication, as previously held; exacerbation of tics is neither clinically significant nor common.
    o Methylphenidate: 2.5 to 30.0 mg/day
    o Dextroamphetamine: 5 to 30 mg/day
  – α₂-Adrenergic agonists
    o Guanfacine
    o Clonidine
      ■ The combination of methylphenidate and clonidine has shown superior efficacy in treating both ADHD and tic symptoms compared to monotherapy with either agent in
one trial.
– Other medications
  o Atomoxetine
  o Desipramine
● Treatment of OCD in patients with tics (6)[B]
  – SSRIs
    o First-line treatment of OCD; can be used in TS as well
    o Side effects include nausea, insomnia, sexual dysfunction, headache, and agitation.
    o Comorbid tic disorder not a contraindication; exacerbation of tics neither clinically significant nor common
    o Black box warning for suicidality with SSRIs
    o Fluoxetine: 10 to 80 mg/day
    o Fluvoxamine: 50 to 300 mg/day
    o Sertraline: 50 to 200 mg/day
  – Tricyclic antidepressants
    o Clomipramine: 25 to 200 mg/day
      ■ Can be used in patients refractory to SSRIs or to augment SSRIs in partial responders
      ■ Side effects: weight gain, dry mouth, lowered seizure threshold, and constipation; ECG changes, including QT prolongation and tachycardia

ADDITIONAL THERAPIES
● Botulinum toxin injections in severe cases or where chronic medication therapy is not preferred
● Habit-reversal training provides a viable tic suppression treatment: works equally for motor and vocal tics.

SURGERY/OTHER PROCEDURES
Thalamic ablation and deep brain stimulation have been used experimentally (7)[C].

COMPLEMENTARY & ALTERNATIVE MEDICINE
Nonpharmacologic therapy
● Reassurance and environmental modification
● Identification and treatment of triggers
● Behavioral therapy: Awareness/assertiveness training, relaxation therapy, habit-reversal therapy, and self-monitoring have shown to significantly decrease tic severity.
● Hypnotherapy
● Biofeedback
● Acupuncture
● Cannabinoids: insufficient evidence to recommend; small trials show small positive effects in some parameters (8)[A].

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
Observe for associated psychiatric disorders.
PATIENT EDUCATION

- Reassurance that many patients with tics do not need medication; often education and/or therapy is all that is required.
- National Tourette Syndrome Association: http://www.tsa-usa.org

PROGNOSIS

- Symptoms will fluctuate throughout illness.
- Tic severity typically stabilizes by age 25 years.
- 60–75% of young adults show some improvement in symptoms.
- 10–40% of patients will exhibit full remission.

REFERENCES

ADDITIONAL READING

CODES

ICD10
F95.2 Tourette’s disorder

CLINICAL PEARLS

- TS is diagnosed by history and witnessing tics; have parent video patient’s tics if not present on exam in your office.
• Many patients require no treatment; patient should play an active role in treatment decisions.
• Nearly 50% of children with tics also have ADHD. Stimulants may be used as first-line treatment for ADHD (tics are not a contraindication, as previously believed).
TOXOPLASMOSIS
Jonathan MacClements, MD, FAAFP

BASICS

- Toxoplasma gondii is an obligate intracellular protozoan parasite.
- Most common latent protozoan infection
- Clinically significant disease typically manifests only in pregnancy or in an immunocompromised patient.

DESCRIPTION

- Acute self-limited infection in immunocompetent
- Acute symptomatic or reactivated latent infection in immunocompromised persons
- Congenital toxoplasmosis (acute primary infection during pregnancy)
- Ocular toxoplasmosis

Pediatric Considerations

- The earlier that a fetal infection occurs, the more severe the resulting disease.
- Risk of perinatal death is 5% if infected in 1st trimester.

Pregnancy Considerations

- Pregnant immunocompromised and HIV-infected women should undergo serologic testing.
- Counsel pregnant women regarding risks of toxoplasmosis.
- Serologic testing during pregnancy is controversial.

EPIDEMIOLOGY

Incidence

- Prevalence of congenital toxoplasmosis in the United States: 10 to 100/100,000 live births
- Predominant sex: male > female

Prevalence

- Present in every country. Seropositivity rates range from <10% to >90% (1)[A].
- In the United States, 11% of individuals ages 6 to 49 years are seropositive.
- Age-adjusted prevalence in the United States is 23%.
- Seroprevalence among women in the United States is 9%.
- Toxoplasmosis is considered one of the neglected parasitic infections of the United States and has been targeted by the Centers for Disease Control (CDC) for public health action.

ETIOLOGY AND PATHOPHYSIOLOGY

- T. gondii has 2 life cycles. The sexual portion of the life cycle is exclusive to felines. The asexual cycle occurs in humans. Cats become infected by eating contaminated meat (birds, mice). Oocysts form within the tract of the cat and are shed in the stool.
- Transmission to humans
  - Ingestion of raw or undercooked meat, food, or water containing tissue cysts or oocytes that is usually from soil contaminated with feline feces
  - Transplacental passage from infected mother to fetus; risk of transmission is 30% on average.
Blood product transfusion or solid-organ transplantation
– Ingested T. gondii oocysts enter host’s gastrointestinal tract where bradyzoites/tachyzoites are released, penetrate contiguous cells, replicate and are transported to susceptible tissues causing clinical disease.

**Genetics**
Human leukocyte antigen (HLA) DQ3 is a genetic marker for susceptibility in HIV/AIDS patients.

**RISK FACTORS**
- Immunocompromised states, including HIV infection with CD4 cell count <100/μL
- Primary infection during pregnancy; risk of fetal transmission increases with gestational age at seroconversion. Transmission in the 1st trimester is associated with more severe consequences.
- Chronically infected immunocompromised pregnant women are at increased risk for transmitting congenital toxoplasmosis.

**GENERAL PREVENTION**
- Avoid eating undercooked meat: Cook to 152°F (66°C) or freeze for 24 hours at ≤−12°C.
- Avoid drinking unfiltered water.
- Wash produce thoroughly.
- Wear gloves and wash hands after gardening and handling soil.
- Wear gloves and wash hands after handling raw meat or cat litter.
- Avoid shellfish (Toxoplasma cysts).

**COMMONLY ASSOCIATED CONDITIONS**
- Chorioretinitis; self-limiting, febrile lymphadenopathy; mononucleosis-like illness
- Potential association with schizophrenia

**DIAGNOSIS**

**HISTORY**
- Congenital toxoplasmosis
  - Clinical presentation varies widely; 80% of patients are asymptomatic at birth.
  - Classic triad (uncommon): chorioretinitis, hydrocephalus, cerebral calcifications
  - Manifestations may include prematurity, intrauterine growth retardation (IUGR).
  - Jaundice, rash with a mononucleosis-like illness
  - Mental retardation, seizures, visual defects, spasticity, sensorineural hearing loss
- Ocular toxoplasmosis
  - Chorioretinitis: focal necrotizing retinitis
  - Yellowish-white elevated cotton patch
  - Congenital disease usually bilateral; acquired is more often unilateral.
  - Symptoms include blurred vision, scotoma, pain, and photophobia.
- Acute toxoplasmosis (immunocompetent host)
  - ~90% of patients are asymptomatic.
  - Most common manifestation is bilateral, symmetric, nontender cervical lymphadenopathy.
  - Constitutional symptoms such as fever, chills, and sweats are usually mild.
– Headaches, myalgias, pharyngitis, hepatosplenomegaly, and diffuse nonpruritic maculopapular rash may occur.
– Pregnant women are often asymptomatic.
– Central nervous system (CNS): encephalitis
– Headache; focal neurologic deficits and seizures
– Fever usually present
– Extracerebral toxoplasmosis: pneumonitis, chorioretinitis; rarely: GI system, liver, musculoskeletal system, heart, bone marrow, bladder, and orchitis

PHYSICAL EXAM
● In adults: fever, lymphadenopathy, nonpruritic maculopapular rash (spares palms and soles); hepatosplenomegaly; visual changes; funduscopic changes
● In newborns: hydrocephalus, neurologic abnormalities, hepatosplenomegaly, chorioretinitis, microcephaly, mental retardation

DIFFERENTIAL DIAGNOSIS
Syphilis, lymphoma, progressive multifocal leukoencephalopathy, cryptococcal meningitis, congenital TORCH infections, HIV; Listeria infection, tuberculosis (TB), tularemia; CMV infection; leukemia; erythroblastosis fetalis

DIAGNOSTIC TESTS & INTERPRETATION
● Complete blood count: atypical lymphocytosis, anemia, thrombocytopenia
● Serology interpretation
  – IgM antibodies appear in the 1st week if acute infection
  – Initial test demonstrates positive IgM and negative IgG, with both tests being positive 2 weeks later.
  – If follow-up IgG is negative 2 to 4 weeks later and IgM is positive, this is likely a false positive.
  – Negative IgG rules out prior infection (IgG persists for life).
● Types of serologic tests
  – ELISA: most commonly used
  – Sabin-Feldman dye test: Gold standard against which all other serologic assays are compared.
  – IFA test: more available in commercial labs
  – ISAGA: widely available commercially; more sensitive and specific than IFA for detecting IgM
  – Avidity testing: confirmatory test to establish if positive IgM/IgG reflects recent or chronic infection
● Polymerase chain reaction (PCR): T. gondii DNA amplification in blood or amniotic fluid; used for diagnosis of fetal infection
● Culture (rarely necessary): Organism can be isolated either by cell culture or by mouse inoculation.

Initial Tests (lab, imaging)
● Diagnosis of primary infection is typically based on history and confirmed by serology.
● Serum Toxoplasma-specific IgG and IgM are first step.
● According to IgM result, determine IgG avidity.
● Diagnosis of maternal infection and congenital toxoplasmosis
– Test pregnant women who have mononucleosis-like illness but negative heterophile test for toxoplasmosis.
– Diagnose maternal infection based on two blood samples at (at least) 2 weeks to show seroconversion.
– High avidity of IgG during 1st trimester argues against maternal primary infection.
– Fetal ultrasound is useful for prognosis.
– Routine screening for toxoplasmosis is not recommended in pregnancy.

• Neonatal diagnosis of congenital toxoplasmosis
  – Serology requires repeat testing for IgM and IgA.
  – Sample cord or peripheral blood within 2 weeks
  – Ophthalmologic, auditory, and neurologic examinations; lumbar puncture and head CT scan

• Diagnosis of toxoplasmic encephalitis
  – Serology for IgG
  – Magnetic resonance imaging (MRI) is more sensitive than CT scan to identify characteristic ring-enhancing lesions.

• SPECT and PET scans can help distinguish toxoplasmosis from CNS lymphoma.

Diagnostic Procedures/Other
• Lymph node biopsy
• Brain biopsy in CNS disease
• Amniocentesis with PCR (risk of false negatives and false positives)
• Placental isolation of Toxoplasma is diagnostic.

Test Interpretation
• Confirmatory, meningocerebritis ± abscesses with necrosis, Giemsa
• Lymph node histology shows triad of:
  – Reactive follicular hyperplasia
  – Irregular clusters of epithelioid histiocytes blurring margins of germinal centers
  – Distension of sinuses with monocytoid cells
• Sensitivity of triad 63%, specificity 91%

 рол

TREATMENT

GENERAL MEASURES
Immunocompetent patients usually require no treatment.

MEDICATION
First Line

ALERT
Important: All pyrimethamine-containing regimens should include leucovorin (folinic acid 10 to 25 mg/day PO) during and 1 week after completion of pyrimethamine to prevent drug-induced hematologic toxicity (2)[A].

• Treatment in immunocompromised hosts
  – Initial regimen of choice is pyrimethamine 200 mg loading dose PO, followed by 50
mg/day plus sulfadiazine 4 to 6 g/day PO in 4 divided doses; for those intolerant or allergic to sulfadiazine, clindamycin 600 to 1,200 mg IV or 450 mg PO QID can be used instead.

- Alternative regimens for patients intolerant to sulfadiazine and clindamycin include the following:
  - Pyrimethamine: 200 mg loading dose PO, followed by 50 mg/day plus azithromycin 900 to 1,200 mg PO once daily
  - Pyrimethamine: 200 mg loading dose PO and then 50 mg/day plus atovaquone 1,500 mg PO BID
  - Sulfadiazine: 1,000 to 1,500 mg QID plus atovaquone 1,500 mg BID
  - Trimethoprim-sulfamethoxazole: 10/50 mg/kg/day PO or IV divided BID (for 30 days) may be a cost-effective alternative.

- Duration of therapy: typically 6 weeks, lower doses for secondary prophylaxis (2)[A]
- Use adjunctive steroids in patients with signs of increased intracranial pressure.
- Anticonvulsants, if there is a history of seizures

Prophylaxis in immunocompromised patients
- Primary prophylaxis: indicated for patients with HIV infection and CD4 count <100 cells/μL who are T. gondii IgG–positive
  - Trimethoprim-sulfamethoxazole-DS: 1 tablet PO daily. Alternative for sulfa allergy is dapsone 50 mg/day PO plus pyrimethamine 50 mg PO weekly plus leucovorin 25 mg PO weekly or atovaquone 1,500 mg PO daily.

Secondary prophylaxis: Following 6 weeks of therapy, administer lower doses of drugs:
  - Sulfadiazine 2 to 4 g/day in 2 to 4 divided doses plus pyrimethamine 25 to 50 mg/day is the first choice.
  - Alternative regimens include clindamycin 600 mg PO q8h plus pyrimethamine 25 to 50 mg/day PO or atovaquone 750 mg PO BID to QID ± pyrimethamine 25 mg PO daily.

Pregnant women (3)[A]
- Although typically offered, it is unsure if antenatal treatment reduces congenital transmission.
  - <18 weeks’ gestation: spiramycin 1 g PO q8h without food until delivery if amniotic fluid PCR is negative; does not treat infection in the fetus
  - >18 weeks’ gestation: Pyrimethamine and sulfadiazine should be considered only if fetal infection is documented by positive amniotic fluid PCR (pyrimethamine is teratogenic):
    - Pyrimethamine: 50 mg PO q12h for 2 days, then 50 mg/day plus sulfadiazine 75 mg/kg PO × 1 dose and then 50 mg/kg q12h (max 4 g/day)

Treat infected newborns regardless of clinical manifestations:
- Pyrimethamine 2 mg/kg/day (max 50 mg) for 2 days; then 1 mg/kg/day (max 25 mg) for 2 to 6 month and then 1 mg/kg (max 25 mg) on Monday, Wednesday, and Friday; sulfadiazine 100 mg/kg/day divided BID; and leucovorin 10 mg 3 times per week during pyrimethamine and 1 week after discontinuation

Immunocompetent nonpregnant patients generally do not require treatment unless symptoms are severe or prolonged; one of two regimens can be used:
- Pyrimethamine: 100 mg loading dose PO, followed by 25 to 50 mg/day plus sulfadiazine 2 to 4 g/day in 4 divided doses
- Pyrimethamine: 100 mg loading dose PO, followed by 25 to 50 mg/day plus clindamycin 300 mg PO QID

Second Line
Clindamycin: 900 to 1,200 mg TID IV used for ocular and CNS toxoplasmosis alone and in combination with pyrimethamine; as effective as the sulfadiazine-pyrimethamine with fewer adverse effects

- Corticosteroids (prednisone 1 to 2 mg/kg/day) are added for macular chorioretinitis or CNS infection.
- Alternatives: atovaquone (Mepron), azithromycin (Zithromax), clarithromycin (Biaxin), or dapsone plus pyrimethamine and leucovorin
- Trimethoprim-sulfamethoxazole appears to be equivalent to pyrimethamine-sulfadiazine in AIDS patients with CNS disease.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Precautions
- Monitor for bone marrow, renal, or liver toxicity.
- Good hydration: Sulfadiazine is poorly soluble and may crystallize in the urine.
- Watch for antibiotic-associated diarrhea.
- Sulfonamides may alter phenytoin and warfarin levels or interfere with oral hypoglycemic agents.

PATIENT EDUCATION

PROGNOSIS
- Immunodeficient patients often relapse if treatment or suppression therapy is stopped.
- Treatment may prevent the development of untoward sequelae in infants with congenital toxoplasmosis.

REFERENCES

ADDITIONAL READING

**CODES**

**ICD10**

- B58.9 Toxoplasmosis, unspecified
- P37.1 Congenital toxoplasmosis
- B58.2 Toxoplasma meningoencephalitis

**CLINICAL PEARLS**

- Toxoplasmosis is typically asymptomatic in immunocompetent patients.
- Primary prevention is important, particularly for pregnant women and immunodeficient patients.
- The most common manifestation of acute toxoplasmosis in immunocompetent host is bilateral, symmetric, nontender cervical lymphadenopathy.
- Universal screening for congenital toxoplasmosis is not currently recommended.
- Serologic testing should be performed at a reference laboratory. CDC recommends the reference laboratory at Palo Alto Medical Foundation Toxoplasma Serology Laboratory. [http://www.pamf.org/serology/External](http://www.pamf.org/serology/External)
TRACHEITIS, BACTERIAL
Mary Cataletto, MD, FAAP, FCCP ● Margaret J. McCormick, MS, RN, CNE

BASICS

DESCRIPTION
- Acute, potentially life-threatening infraglottic bacterial infection following a primary viral infection, usually parainfluenzae or influenza viruses
- Isolated tracheitis is rare. More commonly inflammation affects surrounding tissue (1).
  - Direct laryngoscopy reveals marked subglottic edema and thick mucopurulent secretions, sometimes causing pseudomembranes.
- System(s) affected: pulmonary
- Synonym(s): laryngotracheobronchitis; pseudomembranous croup; bacterial croup

EPIDEMIOLOGY

Incidence
- Estimated incidence: 4 to 8 per 1 million (2)
- Approximately 0.1/100,000 children-years in United Kingdom (1)
- First cases described prior to 1950; resurgence of cases has been noted since 1979.
- Peak incidence in children: fall and winter
- Mean age: 5 years (2)
- Infections in adolescents and adults have been reported.
- Predominant sex: male > female (2:1)
- Accounts for 5–14% of upper airway obstruction in children requiring critical care services

Prevalence
- Rare illness
- Most common potentially life-threatening upper airway infection in children
- Methicillin-resistant Staphylococcus aureus (MRSA) may contribute to changing epidemiology and virulence.

ETIOLOGY AND PATHOPHYSIOLOGY

- S. aureus (most common pediatric cause): Consider MRSA.
- Haemophilus influenzae type B
- Streptococcus pyogenes group A
- Streptococcus pneumoniae
- Moraxella catarrhalis (associated with higher intubation rate; more frequent in younger children)
- Frequently polymicrobial

Genetics
No known genetic predisposition

RISK FACTORS
- Periods of increased seasonal activity of respiratory viruses
Reports following adenoidectomy, with chronic tracheal aspiration, with evidence of other concurrent infections, including sinusitis, otitis, pneumonia, or pharyngitis

GENERAL PREVENTION
- Standard precautions, with scrupulous attention to hand washing
- Vaccination against viruses that may predispose to bacterial tracheitis
- In children with artificial airways, periodic surveillance of tracheal cultures can be helpful.

COMMONLY ASSOCIATED CONDITIONS
- Consider anatomic abnormalities or foreign body as well as recent pharyngeal or laryngeal surgery.
- Predisposing: Down syndrome, immunodeficiency, subglottic hemangioma, tracheoesophageal fistula repair, tracheobronchomalacia
- Viral coinfection may occur.

DIAGNOSIS
- May present with fever and systemic toxicity or as more localized disease
- Careful history and physical exam are the best methods to distinguish bacterial tracheitis from croup and other rare causes of upper airway obstruction.

HISTORY
- Prodromal upper respiratory tract symptoms
- Gradual progression of mild upper airway symptoms over 1 hour to 6 days to acute, febrile phase of rapid respiratory decompensation
- No drooling
- No response to aerosolized epinephrine and/or systemic corticosteroids (2)
- May see more indolent course in patients with artificial airways

PHYSICAL EXAM
Fever >38°C (100.4°F)
- Toxic appearance
- Variable degree of respiratory distress (1,3)
  - Cough
  - Tachypnea
  - Inspiratory stridor
- Voice and cry usually normal
- Drooling uncommon

DIFFERENTIAL DIAGNOSIS
- Severe croup (viral)
- Spasmodic croup
- Diphtheria in nonvaccinated patients
- Retropharyngeal abscess
- Epiglottitis
- Bacterial pneumonia
- Foreign body aspiration
- Angioneurotic edema
DIAGNOSTIC TESTS & INTERPRETATION

- Routine laboratory studies are not required to make the diagnosis.
- Radiographs are neither definitive nor diagnostic.
- Tracheal endoscopy provides a definitive diagnosis (2)[C].

Initial Tests (lab, imaging)

- Bacterial cultures of tracheal secretions are required for culture isolates and sensitivities.
- Rapid antigen or polymerase chain reaction (PCR)-based testing for respiratory viruses may be helpful.
- Routine laboratory studies may not be helpful.
- Blood cultures rarely positive
- CBC results may vary.
  - WBC count may show marked leukocytosis or may be normal.
  - Increased band cell count
- Radiographs may be normal, but exudates may mimic the findings in foreign body aspiration.
- Pneumonic infiltrates are common.
- Anteroposterior (AP) and lateral neck x-rays show subglottic and tracheal narrowing (i.e., steeple sign on AP film) with haziness and radiopaque linear or particulate densities (crusts).
- In patients with risk of acute respiratory obstruction, either do not obtain x-rays or monitor carefully.

Follow-Up Tests & Special Considerations
Follow chest film if suspect pneumonia.

Diagnostic Procedures/Other

- Direct laryngoscopy and tracheoscopy is diagnostic and demonstrates
  - Normal supraglottic structures
  - Marked subglottic erythema and edema
  - Ulcerations
  - Epithelial sloughing
  - Copious mucopurulent secretions ± plaques or pseudomembranes
- Obtain Gram stain and aerobic, anaerobic, and viral cultures of tracheal secretions during the procedure.
- Tracheal biopsy is rarely indicated but may be considered in immunodeficient child or child with ulcerative colitis.

Test Interpretation

- Diffuse inflammation of larynx, trachea, and bronchi
- Mucopurulent exudate; microabscesses may be present.
- Semiadherent membranes (containing numerous neutrophils and cellular debris) may be identified within the trachea.

TREATMENT

- Treat as potentially life-threatening airway emergency.
- Children with suspected or actual bacterial tracheitis should be cared for in a pediatric ICU (2)[C].
Assess and monitor respiratory status; supplemental oxygen may be required.
Airway protection and support, as necessary (at least 50% require intubation; some studies report up to 100%)
Ventilatory support may be required.
Suctioning

MEDICATION
Empiric therapy should cover the most common pathogens until sensitivities are available: antistaphylococcal agent (vancomycin or clindamycin) and a 3rd-generation cephalosporin (e.g., ceftriaxone or cefotaxime) (2)[C].
In the case of technology-dependent children with tracheostomy, make initial antibiotic choices based on previous tracheal culture.
Narrow regimen when pathogens and sensitivities available (2)[C].
Inhaled antibiotics are not routinely recommended either as primary or adjuvant therapy (4)[A].

Contraindications: Refer to the manufacturer’s literature for each drug.
Precautions: Refer to the manufacturer’s literature for each drug. Avoid aminoglycosides in patients with previous hearing loss.
Significant possible interactions: Refer to the manufacturer’s literature for each drug.

ISSUES FOR REFERRAL
All children with suspected or actual bacterial tracheitis should be cared for in a pediatric ICU; ID and ENT consultation should be considered.

ADDITIONAL THERAPIES
At present, evidence is lacking to establish the effect of heliox inhalation in the treatment of croup in children.
For technology-dependent children with artificial airway:
– Initial antibiotic choices should cover most recent tracheal aspirate isolates and then be refined according to culture and sensitivity results.

SURGERY/OTHER PROCEDURES
Tracheostomy is usually not necessary.
Therapeutic bronchoscopy may be necessary to facilitate removal of inspissated secretions.
Tracheal membranes may require removal.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Aggressive supportive care and airway protection are paramount.
Initial treatment of choice for bacterial tracheitis is broad-spectrum antibiotic coverage.
Children with tracheitis and artificial airways present unique challenges: Tracheoscopy is important in establishing diagnosis in this population.
Be vigilant for possible MRSA.

Pediatric Considerations
True pediatric emergency
Admission to ICU
Maintain airway: often difficult due to copious secretions
– Endotracheal or nasotracheal intubation usually needed, especially in infants and children
Vigorous pulmonary toilet to clear airway of secretions
Hydration, humidification, antibiotics
Admission criteria/initial stabilization
– Suspected or confirmed diagnosis of tracheitis
– Respiratory distress
– Artificial airway
Nursing
– Provide calm, quiet environment for child once endoscopy and cultures are done.
– Airway monitoring
– Frequent suctioning
– Monitor fluid balance.
– Establish and maintain open lines of communication with child and parents.
Discharge when no longer in need of acute care.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Children with artificial airways will require ongoing follow-up.

DIET
Varies with clinical situation

PATIENT EDUCATION
Keep immunizations up to date.

PROGNOSIS

Intubation generally 3 to 11 days
Usually requires 3 to 7 days of hospitalization
With effective early recognition and management, complete recovery can be expected.
Cardiopulmonary arrest and death have occurred.
Higher recurrence rates in children with artificial airways

COMPLICATIONS

Cardiopulmonary arrest
Hypotension
Acute respiratory distress syndrome (ARDS)
Pneumonia
Sepsis (1)
Formation of pseudomembranes
Postinfectious stenosis (long term) (1)

Croup (Laryngotracheobronchitis); Epiglottitis

CODES
ICD10
- J04.10 Acute tracheitis without obstruction
- J04.11 Acute tracheitis with obstruction
- J05.0 Acute obstructive laryngitis [croup]

CLINICAL PEARLS
- Bacterial tracheitis is an acute, potentially life-threatening, infraglottic bacterial infection following a primary viral infection that accounts for 5–14% of upper airway obstructions in children requiring critical care services.
- Children with suspected or actual bacterial tracheitis should be cared for in a pediatric ICU.
- Endoscopy provides a definitive diagnosis (3).
- Initial treatment of choice for bacterial tracheitis is broad-spectrum antibiotic coverage, aggressive airway protection, and supportive care (3).
BASICS

DESCRIPTION

- Society’s growing acceptance of nontraditional lifestyles has, in recent years, made increased room for transgender individuals, as it has for lesbians, gays, and bisexuals, even as these populations continue to suffer unique health care disparities. Better education of physicians and other providers will improve the health of the transgender population. Such education begins with teaching acceptance of all human beings into health care and ensuring a safe office environment for transgender individuals to speak openly with their clinicians. Once a “safe” space is created, it will be possible to provide appropriate and supportive health care to reduce inequities and the harms and disparities in health outcomes that result.
- At least 1:11,900 males and 1:30,400 females in the United States define themselves as transgender.
- Current estimates indicate 0.6% of U.S. adults, or some 1.4 million people, identify themselves as transgender, a 2-fold increase since 2011 (1). Transgender identification is more common among those age 18–24, with a rate of 0.7%, and self-identification occurs at an early age, with 94% of respondents to the 2015 United States Transgender Survey saying that by age 20 they felt that their gender was different from that assigned at birth, with 73% considering themselves transgender by that age (2).
- The terms “transgender” and “gender nonconforming” (GNC), or, more inclusively, TGNB, or transgender and gender non-binary, refer to those whose gender identity or presentation differs from the sex assigned at birth (2,3).
- Gender identity, the sense of one’s self as male or female, and especially gender presentation, the outward expression of gender, may or may not reflect the self-identification of a TGNB patient.
- Transgender patients can no more be categorized or thought alike than any other patients. Race, ethnicity, socioeconomic status, age, and other factors all play a role in how transgender patients define themselves.
- Moreover, a patient’s body may or may not match gender identity or presentation. Although a patient’s anatomy may determine treatment, that treatment must also be sensitive to, and respect, gender identity and/or presentation.
- Transgender status says nothing about an individual’s sexual orientation. Transgender people may be sexually oriented toward men, women, other transgender people, or any combination of the above.
- TGNB patients are further defined by those who have undergone surgical procedures and/or medical treatment to better align gender identity, by those who plan such procedures in the future, and by others who do not.

Accordingly, it is important to ask transgender patients how they would describe themselves and to honor terminology acceptable to each patient, specifically preferred name, preferred pronoun, and preferred gender identity, with those attributes ideally reflected within any electronic medical record (EMR). A two-question approach—first asking current gender, then inquiring after the sex assigned at birth—has been validated and shown to avoid stigmatizing
TGNB patients and to encourage provider–patient conversations (2).

- Transgender people have a unique set of mental and physical needs (4).
  - Real or imagined stigma and discrimination are barriers to health care (3).
  - Transgender patients are less likely to have health insurance and more likely to encounter discrimination on the part of health care providers, thereby limiting access to health care services.
  - >50% of transgender patients delay needed care, compared to 20% in the general population (3).
  - 91% of TGNB patients want counseling, hormones, and/or puberty blockers, even though only 65% ever get any of these (2).

- Evidence-based medicine for transgender patients is lacking or limited to case reports and smaller studies aggravated, perhaps, by social stigma, marginalization, and discrimination (4).

- Transgender patients may also suffer from gender dysphoria, recognized in Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) as the disconnection between gender expression and one’s assigned gender at birth.

**DIAGNOSIS**

- **Specific health concerns**
  - Transition-related medical care, or gender-confirming therapy, including hormone therapy and surgical treatment, or gender-confirming surgery (GCS), help patients align primary and secondary sexual characteristics with gender identity (4).
  - The World Professional Association for Transgender Health (WPATH) has published standards of care (SOCs) that include hormone therapy and SRS (4)[C].
    - SOCs are endorsed by American College of Obstetricians and Gynecologists (ACOG), the Endocrine Society, the American Medical Association, and the American Psychological Association (4).
    - Hormone therapy and surgery not only treat symptoms of gender dysphoria but also help TGNB patients achieve well-being.
    - Hormone therapy does convey a greater risk of thromboembolic disease, liver dysfunction, and cardiovascular (CV) disease.
    - Treatment is associated with a high degree of patient satisfaction, low prevalence of regrets, and significant relief of gender dysphoria (4)[C].

- **Specific diseases**
  - AIDS
    - Rate of HIV infection among transgender people is 4 times that of general population in the United States. Worldwide, the prevalence may be 50 times higher than the background rate (1).
    - Requires increased vigilance on the part of health care providers

- **Psychosocial considerations**
  - TGNB people are at risk of victimization by others, of mental health issues, including depression and anxiety, and of suicide.
    - 41% of transgender people have attempted suicide compared to 1.6% of the U.S. general population (4).
    - One 2012 survey found that 61% of transgender people had been victims of physical assault and abuse; 64% had been victims of sexual assault, mostly not reported.
- TGNB people are at greater risk of societal discrimination including housing and workforce discrimination and are more likely to be unemployed, homeless, and lacking in social support owing to federal and state laws that inadequately protect transgender people from discrimination. The resulting social marginalization contributes to poor well-being overall, aggravated by limited access to quality health services (3).
  - Psychosocial assessment is recommended at baseline and at least annually.
  - Mental health and substance abuse screening are also indicated.

**ALERT**
- Transgender patients are at increased risk of suicidal ideation, suicide attempts, and suicide (4).
- Improving access to care
  - Barriers to health care and the need for respectful, supportive, and inclusive clinic environments
    - TGNB patients are often reluctant to disclose gender identity or expression, owing to the risk of stigma or discrimination.
    - 28% of transgender patients report being verbally harassed and 2% physically assaulted while seeking health care.
  - Providers’ lack of education and experience and addressing that knowledge gap and any cultural insensitivity
  - Financial barriers
    - Lack of health insurance
    - Unemployment among transgender people is twice the rate of general population.

**TREATMENT**

**GENERAL MEASURES**
- Care of TGNB people, including hormone therapy, is within the scope of primary care providers.
- Education of health care providers, for physicians, and those beginning in medical school, is crucial to providing optimal care to transgender patients, and the lack of such education is a significant barrier to care for transgender individuals (1,4).

**MEDICATION**

**First Line**
- Gender-affirming hormone therapy (5)[A]

- **Adolescents**
  - Suppress pubertal development using gonadotropin-releasing hormone (GnRH) analogues when girls and boys first exhibit pubertal physical changes (Tanner stage 2).
  - Progestin
  - Cross-sex steroids at about age 16 years
  - Initiate treatment after persistent gender dysphoria/gender incongruence have been confirmed by a multidisciplinary team of medical and mental health providers and the patient has the mental capacity to provide informed consent, generally by age 16 years.
  - Surgical referral
- **Adults**
– Estrogens, antiandrogens, and/or GnRH agonists for male-to-female patients
  o Estradiol orally 2 to 6 mg/day, or estradiol transdermal patch 0.025 to 0.200 mg/day, or estradiol valerate or cypionate 5 to 30 mg IM every 2 weeks
  o Add spironolactone 100 to 300 mg/day, cyproterone acetate 25 to 50 mg/day, or GnRH agonists to minimize estrogen requirement.
  o At initial visit, do prostate-specific antigen (PSA), lipid panel, and liver function tests (LFTs); every 3 months, check testosterone levels until stable, monitor estradiol blood level for compliance, repeat lipid panel, and encourage breast exams.
  o Every 6 months to 1 year, preoperatively, order visual fields to assess for prolactinoma, check serum prolactin, and repeat lipid panel; if patient is >50 years old, recheck PSA and consider mammogram.
  o Every 6 months to 1 year, postoperatively, reduce estrogens to hormone replacement therapy (HRT) doses (conjugated equine estrogens 0.625 mg/day, transdermal ethinyl estradiol 0.05 to 0.10 mg/day, or ethinyl estradiol 0.02 to 0.05 mg/day) and do dual energy x-ray absorptiometry (DEXA) scan to monitor for osteoporosis.
– Testosterone for female-to-male patients
  o Testosterone esters 100 to 200 mg IM every other week or transdermal testosterone 2.5 to 7.5 mg/day or testosterone gel 1.6% 50 to 100 mg/day with goal of serum testosterone in midmale range
  o At initial visit, check weight, lipid panel, and glucose level.
  o Every 3 to 6 months, repeat lipid panel and LFTs, do complete blood count to rule out polycythemia, and check testosterone levels.
  o Preoperatively, do pelvic exam and Papanicolaou (Pap) smear per current protocols.
  o Every 2 years, do endometrial ultrasounds.
  o Every 6 months to 1 year, postoperatively, titrate testosterone to maintain serum testosterone at 500 μg/dL (17.35 SI) and consider DEXA scans per protocol.

SURGERY/OTHER PROCEDURES
● GCS only after 1 year of hormone therapy (5)
● In adolescents, consider delaying gender-confirming genital surgery until the patient is at least 18 years old.
● The rate of GCS is increasing, with some 25% of transgender patients having undergone some form of GCS (2).
● GCS has a positive impact on individual health in that it improves mental health and results in higher quality of life and higher socioeconomic status. It also enhances public health by increasing cultural awareness and decreasing social stigma (6).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Interacting with the health care system
● Discrimination on the part of health care providers is a major barrier to care.

Patient Monitoring
● Routine medical screening:
  – Pelvic exam
- Cervical and anal Pap tests
- Screening for STIs
- Measurement of prolactin levels
- Evaluation of CV risk factors
- Bone mineral density tests, as indicated
- Breast cancer screening per guidelines
- Screening, as indicated, for prostate cancer in transgender females treated with estrogens
- In adolescents, monitor clinical pubertal development every 3 to 6 months and check labs (LH, FSH, E2/T, 25[OH]D) every 6 to 12 months; do bone mineral density test every 1 to 2 years.
- In adults, monitor physical changes and any adverse changes every 3 months during the 1st year of hormone therapy and then once or twice yearly.
- Transgender males: Check serum testosterone every 3 months until levels are in the normal physiologic male range; check hematocrit and hemoglobin at baseline and every 3 months in year 1 and then once or twice a year; monitor lipids as indicated.
- Transgender females: Check serum testosterone and estradiol every 3 months; if patient is on spironolactone, check serum electrolytes every 3 months in the 1st year of treatment and then annually.

PATIENT EDUCATION
- Hormone therapy and potential health risks
- Counseling for gender-confirming surgery
- Legal issues
  - Under the Affordable Care Act (ACA), denial of treatment of being transgender as a “preexisting condition” is banned (4).
  - Since 2014, Centers for Medicare & Medicaid Services (CMS) has been providing transition-related coverage (6).
  - The U.S. Department of Veterans Affairs (VA), although acknowledging the need to care for transgender veterans, denies coverage of GCS on the basis of a VA regulation that excludes gender alterations from the medical benefits package (4).

- Z72.52 High risk homosexual behavior

CLINICAL PEARLS

- Health care providers must be sensitive to the unique needs of transgender patients; must be open to the care of such patients; and should, as with all patients, display an ethical, principled, and timely approach to care.
- Do use inclusive language in the care of transgender patients, assessing the individuals’ preferences, and respect differences among transgender patients.
- Always address health care needs particular to the transgender population.
- Avoid stigmatization of transgender patients, ensuring gender-blind clinical care.
TRANSIENT ISCHEMIC ATTACK (TIA)
Samuel E. Mathis, MD

BASICS

DESCRIPTION
● A transient episode of neurologic dysfunction due to focal brain, retinal, or spinal cord ischemia without acute infarction
● Most important predictor of stroke: 15% of patients with stroke report previous TIA.
● Synonym(s): ministroke

EPIDEMIOLOGY
Incidence
200,000 to 500,000 new TIA cases reported each year
● 83 cases per 100,000 people/year in the United States
● 400 to 800 cases per 100,000 persons ages 50 to 59 years

Prevalence
● Prevalence of TIA in general population: ~2.3%
● Predominant age: Risk increases >60 years; highest in 7th and 8th decades
● Predominant sex: male > female (3:1)
● Predominant race/ethnicity: African Americans > Hispanics > Caucasians. The difference in African Americans is exaggerated at younger ages.

ETIOLOGY AND PATHOPHYSIOLOGY
Temporary reduction/cessation of cerebral blood flow adversely affecting neuronal function
● Carotid/vertebral atherosclerotic disease
  – Artery-to-artery thromboembolism
  – Low-flow ischemia
● Small, deep vessel disease associated with hypertension (HTN)
  – Lacunar infarcts
● Cardiac diseases
  – 1–6% of patients with myocardial infarction (MI) develop stroke.
● Embolism secondary to the following:
  – Valvular (mitral valve) pathology
  – Mural hypokinesias/akinesias with thrombosis (acute anterior MI/congestive cardiomyopathies)
  – Cardiac arrhythmia (atrial fibrillation accounts for 5–20% incidence)
● Hypercoagulable states
  – Antiphospholipid antibodies
  – Increased estrogen (e.g., oral contraceptives)
  – Pregnancy and parturition
● Arteritis
  – Noninfectious necrotizing vasculitis
  – Drugs
  – Irradiation
– Local trauma
  • Sympathomimetic drugs (e.g., cocaine)
  • Other causes: spontaneous and posttraumatic (e.g., chiropractic manipulation) arterial dissection
  • Fibromuscular dysplasia

Genetics
Inheritance is polygenic, with tendency to clustering of risk factors within families.

RISK FACTORS
  • HTN
  • Cardiac diseases (atrial fibrillation, MI, valvular disease)
  • Diabetes
  • Hyperlipidemia
  • Atherosclerotic disease (carotid/vertebral stenosis)
  • Cigarette smoking
  • Thrombophilias

GENERAL PREVENTION
  • Lifestyle changes: smoking cessation, diet modification, weight loss, regular aerobic exercise, and limited alcohol intake
  • Strict control of medical risk factors: diabetes (glycemic control), HTN (thiazide and/or ACE/ARB), hyperlipidemia (statins), anticoagulation when high risk of cardioembolism (e.g., atrial fibrillation, mechanical valves)
  • Causation is key to preventing recurrence (1).

Alert
  • 10–20% of patients with TIA have cerebrovascular accident (CVA) within 90 days; up to 80% of this risk is preventable (2).
  • 25–50% of those occur within the first 48 hours.

Geriatric Considerations
  • Older patients have a higher mortality rate—highest in 7th and 8th decades.
  • Atrial fibrillation is a frequent cause among the elderly.

Pediatric Considerations
  • Congenital heart disease is a common cause among pediatric patients.
  • Other causes include the following:
    – Metabolic: homocystinuria, Fabry disease
    – Central nervous system infection
    – Clotting disorders
    – Genetic: Marfan syndrome, moyamoya, or sickle cell disease

Pregnancy Considerations
  • Preeclampsia, eclampsia, and HELLP syndrome
  • Thrombotic thrombocytopenic purpura (TTP) and hemolytic uremic syndrome
  • Postpartum angiopathy
  • Cerebral venous thrombosis
  • Hypercoagulable states related to pregnancy
COMMONLY ASSOCIATED CONDITIONS

- Atrial fibrillation (uncommon)
- Uncontrolled HTN (common)
- Carotid stenosis (common)
- TIA mimics
  - Some disease processes mimic TIA presentation.
  - Seizures, migraines, metabolic disturbances, syncope
  - Difference: gradual onset with nonspecific symptoms (headache, memory loss) vs. acute onset with specific neurologic deficits (TIA)

DIAGNOSIS

HISTORY

- Emphasis on symptom onset, progression, and recovery
- Carotid circulation (hemispheric): monocular visual loss, hemiplegia, hemianesthesia, neglect, aphasia, visual field defects (amaurosis fugax); less often: headaches, seizures, amnesia, confusion
- Vertebrobasilar (brain stem/cerebellar): bilateral visual obscuration, diplopia, vertigo, ataxia, facial paresis, Horner syndrome, dysphagia, dysarthria; also headache, nausea, vomiting, ataxia
- Past medical history, baseline functional status
- ABCD2 or ABCD3-I score: predicts 48-hour CVA risk (3)[B]
  - Score of 0 to 1: 0%; 2 to 3: 1.3%; 4 to 5: 4.1%; 6 to 7: 8.1%
    - Age >65 years: 1 point
    - Blood pressure (BP) 140/90 mm Hg: 1 point
    - Clinical presentation
      ■ Unilateral weakness: 2 points
      ■ Speech impaired without weakness: 1 point
    - Duration: 1 to 2 points based on time
    - Diabetes: 1 point
    - Dual TIA (within 7 days preceding): 2 points
    - Imaging (new lesion or carotid stenosis): 2 points

PHYSICAL EXAM

- Vital signs, oxygen saturation
- Thorough neurologic and cardiac exams

DIFFERENTIAL DIAGNOSIS

- Evolving stroke
- Migraine (hemiplegic)
- Focal seizure (Todd paralysis)
- Bell palsy
- Neoplasm of brain
- Subarachnoid hemorrhage
- Intoxication
- Glucose or other electrolyte abnormalities
- Head trauma
- Central nervous system infection
- Multiple sclerosis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Neuroimaging within 24 hours of symptom onset
- Magnetic resonance imaging (MRI), including diffusion-weighted imaging, is the preferred brain diagnostic modality to rule out stroke; if not available, then noncontrast head CT scan (4)[B]
- Noninvasive imaging of the cervicocephalic vessels should be performed routinely in suspected TIA by carotid ultrasound/TCD, magnetic resonance angiography, or computed tomography angiography depending on availability and expertise and characteristics of the patient (4)[B].
- Routine blood tests (CBC, chemistry, prothrombin time/partial thromboplastin time, UPT, coagulation screen, fasting lipid panel, ECG) are reasonable in evaluation of patient with TIA (1,4)[B].

**Follow-Up Tests & Special Considerations**

- Transesophageal Echo (TEE) is useful in identifying patent foramen ovale (PFO), aortic arch atherosclerosis, and valvular disease (4)[B].
- Prolonged cardiac monitoring is useful in patients with an unclear etiology after initial brain imaging and ECG (4)[B].
- EEG: if seizure suspected

**TREATMENT**

**GENERAL MEASURES**

- TIA is a neurologic emergency. Immediate medical attention should be sought within 24 hours of symptom onset due to increased stroke risk.
- Current evidence suggests that patients with high-risk TIA’s require rapid referral and a 24-hour admission for observation and work-up (ABCD2 score ≥3).
- Outpatient investigations may be considered based on patient’s stroke risk, arrangement of follow-up, and social circumstances.
- Antiplatelet therapy to prevent recurrence or future CVA
- Treatment/control of underlying associated conditions

**MEDICATION**

- For patients with TIA, the use of antiplatelet agents rather than oral anticoagulation is recommended to reduce risk of recurrent stroke and other cardiovascular events, with the exception of cardioembolic etiologies (4)[A].
- Uncertain if switching agent in patients who have additional ischemic attacks while on antiplatelet therapy is beneficial (5)[C].

**First Line**

- Enteric-coated aspirin: 160 to 325 mg/day in the acute phase (5)[A] followed by long-term
antiplatelet therapy for noncardioembolic TIA and anticoagulation for cardioembolic etiology

- **Antiplatelet therapy**
  - Aspirin 81 to 325 mg/day (5)[A]
    o Contraindications: active peptic ulcer disease and hypersensitivity to aspirin or NSAIDs
    o Precautions: may aggravate preexisting PUD or worsen symptoms of asthma
    o Significant possible interactions: may potentiate effects of anticoagulants and sulfonylurea analogues
  - ER dipyridamole–aspirin (Aggrenox): 25/200 mg BID (5)[B]
    o Combined therapy with dipyridamole and aspirin not proven to have greater efficacy (1)
    o More expensive than aspirin alone and may have more associated side effects
  - Clopidogrel 75 mg/day (5)[B]
    o Can be used in patients who are allergic to aspirin (5)[B]
    o Precautions: TTP can occur and increases risk of bleeding when combined with aspirin.
    o May be very slightly more effective than aspirin alone (5)[B]; more expensive and more side effects than aspirin

- **Anticoagulation therapy**
  - Direct thrombin inhibitor:
    o Dabigatran (Pradaxa)
    o Idarucizumab (Praxbind) reversal agent
  - Factor Xa inhibitors
    o Apixaban (Eliquis)
    o Rivaroxaban (Xarelto)
    o Edoxaban (Savaysa)
      ■ Noninferior to warfarin in nonvalvular atrial fibrillation
      ■ Precautions: Avoid in CKD (CrCl <30 mL/min).
      ■ Expensive but no INR needed
      ■ Not reversible
  - Warfarin (INR-adjusted dose) (5)[A]
    o Contraindications: intolerance/allergy, active liver disease, active bleeding, pregnancy
    o Significant possible interactions: antibiotics, antiepileptics, antifungals, and many others
  - Aspirin 325 mg/day or aspirin 81 mg/day plus clopidogrel 75 mg/day (5)[A]
    o Reserved for patients who cannot take anticoagulation for reasons other than bleeding risk

---

**Second Line**

Ticlopidine (Ticlid): 250 mg PO BID

- For patients unable to tolerate other agents
  - Contraindications: hypersensitivity, presence of hematopoietic/hemostatic disorders, conditions associated with bleeding, severe liver dysfunction
  - Precautions: neutropenia (0.8% severe), which is reversible with cessation of the drug. Monitor blood counts every 2 weeks for first 3 months. TTP can occur.
  - Significant possible interactions: Digoxin plasma levels decreased 15%; theophylline half-life increased from 8.6 to 12.2 hours.

**ISSUES FOR REFERRAL**
Neurology for ongoing workup and treatment
Cardiology if cardiac cause suspected
Vascular surgery if carotid endarterectomy appropriate

ADDITIONAL THERAPIES
Secondary prevention of TIA should be initiated; venous thromboembolism (VTE) prophylaxis
Patients with TIA or ischemic stroke should be started on high-dose statin (1).
BP should be reduced after 24 hours. Thiazides, ACE inhibitors, and angiotensin receptor blockers have shown to be of benefit. β-Blockers have not shown benefit in reducing recurrence or stroke.
Patients with Diabetes Mellitus (DM) or pre-DM should be advised to follow American Diabetes Association guidelines to maintain tight glycemic control.

SURGERY/OTHER PROCEDURES
Consider carotid endarterectomy in patients with a high degree of carotid artery stenosis ≥70%.
When carotid endarterectomy is indicated for patients with TIA, surgery within 2 weeks is reasonable if there are no contraindications to early revascularization.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Encourage patients to improve dietary and lifestyle habits to reduce their risk of recurrent TIA or stroke.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Symptoms <72 hours and the following:
- ABCD2 score of >3
- ABCD2 score of 0 to 3 and uncertainty that diagnostic workup can be completed within 2 days as outpatient. Alternatively: If urgent imaging not available through emergency department or urgent neurology follow-up not available, admit ABCD2 score ≥3 with evidence of focal ischemia.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Follow-up with neurologic support every 3 months for 1st year and then annually
- Close attention to recurrent TIA or subsequent CVA

DIET
- DASH diet or as appropriate for medical problems
- Physical activity
  - Any level of physical activity is beneficial, but at least 30 minutes of moderate-intensity physical activity daily is preferred (150 minutes/week).

PROGNOSIS
- The risk of stroke on the ipsilateral side within 90 days and cumulative thereafter is 10–20%.
- Risk increases based on multiple risk factors.
- Patients with larger artery occlusion or cardioembolic etiology are at increased risk of
High mortality risk associated with TIA, up to 25% of patients will die within 1 year of TIA.

**COMPLICATIONS**

Stroke and functional impairment

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

Algorithms: Stroke; Transient Ischemic Attack and Transient Neurologic Defects
CODES

ICD10
- G45.9 Transient cerebral ischemic attack, unspecified
- G45.1 Carotid artery syndrome (hemispheric)
- G45.0 Vertebro-basilar artery syndrome

CLINICAL PEARLS
- Utilize the ABCD2 scoring system for admission criteria.
- Encourage smoking cessation, exercise, weight loss, limited ETOH intake, and control of HTN, hyperlipidemia, and diabetes.
- Antiplatelet therapy (e.g., aspirin, clopidogrel, or aspirin-clopidogrel) should be initiated.
- Warfarin should be initiated in patients with atrial fibrillation or cardioembolic risk factors.
BASICS

DESCRIPTION

- Transient stress cardiomyopathy (TSC) is a unique cause of reversible left ventricle (LV) dysfunction with a presentation indistinguishable from the acute coronary syndromes (ACS), particularly ST-segment elevation myocardial infarction (STEMI) (1).
- Typically, the patient is a postmenopausal woman who presents with acute chest pain, dyspnea, or syncope and an identifiable “trigger” (i.e., an acute emotional or physiologic stressor).
- First reported by authors from Japan as takotsubo cardiomyopathy, the Japanese word for octopus trap, due to the characteristic shape of the LV at the end of systole. It has been described under numerous names in the literature including “broken heart syndrome,” “stress cardiomyopathy,” and “apical ballooning syndrome.”
- Presenting clinical features include the following:
  - Chest pain/pressure, dyspnea and/or syncope
  - ECG changes, including ST-segment elevations or diffuse T-wave inversions
  - Mild elevation in cardiac biomarkers (creatine kinase [CK], troponin)
  - Transient wall motion abnormalities that may involve the base, midportion, and/or lateral walls of the LV
  - The apex of the right ventricle (RV) may be affected in up to 25% of cases (1)[B].
- Clinical features may vary on a case-by-case basis, and formal diagnostic criteria have not been established.
- Authors from the Mayo Clinic have proposed that three of the four following criteria establish the diagnosis (1)[A]:
  - Transient akinesia or dyskinesis of the LV apical and midventricular segments with regional wall motion abnormalities extending beyond a single epicardial vascular distribution
  - Absence of obstructive coronary artery disease (CAD) or angiographic evidence of acute plaque rupture
  - New ECG abnormalities, either ST-segment elevation or T-wave inversion
  - Absence of
    - Recent significant head trauma
    - Intracranial bleeding
    - Pheochromocytoma
    - Obstructive epicardial CAD
    - Myocarditis
    - Hypertrophic cardiomyopathy
- Synonym(s): takotsubo cardiomyopathy; apical ballooning syndrome; stress cardiomyopathy; broken heart syndrome; ampulla cardiomyopathy

EPIDEMIOLOGY
**Incidence**
- TSC accounts for an estimated 1–3% of all and 5–6% of female patients presenting with suspected STEMI.
- In a recent prospective evaluation of patients admitted to the ICU, as many as 28% had apical ballooning, often in association with sepsis.
- Predominant sex: 82–100% of cases occur in women.
- Predominant age: Mean age of patients is 62 to 75 years.

**Prevalence**
2.2% of patients presenting to a referral hospital with ST-segment MIs were found to have TSC.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- The precise pathophysiologic mechanisms of TSC are not well understood.
- There is considerable evidence that sympathetic stimulation is central to its pathogenesis. A clear emotional or physiologic triggering event precipitates the syndrome in most cases, and TSC has been associated with conditions of catecholamine excess (e.g., pheochromocytoma, central nervous system disorders) and activated specific cerebral regions (1).
- Occurs primarily in subjects with increased susceptibility of the coronary microcirculation and of cardiac myocytes to stress hormones leading to temporary left ventricular dysfunction with secondary myocardial inflammation (1).
- A perturbation in the brain–heart axis, originating in the insular cortex, may be the inciting event (2).
- Subsequent overwhelming activation of the sympathetic nervous system initiates a cascade of events, including the following:
  - Catecholamine-induced LV dysfunction: “biased agonism” of epinephrine for β2-adrenergic receptors, located predominantly at the cardiac apex
  - Endothelial dysfunction and vasospasm
  - Cellular metabolic injury
    - Myocardial norepinephrine release
    - Calcium overload
    - Contraction band necrosis

**Genetics**
No genetic associations have been described to date.

**RISK FACTORS**
- Female sex
- Postmenopausal state
- Emotional stress (i.e., argument, death of family member), more common in women
- Physiologic stress (i.e., acute medical illness), more common in men
- Chronic neurologic or psychiatric disease (2)

**COMMONLY ASSOCIATED CONDITIONS**
Death from TSC is rare, and most cases resolve rapidly, within 2 to 3 days. Reported complications include:
- Left-sided heart failure
- Pulmonary edema
- Cardiogenic shock and hemodynamic compromise
Dynamic LV outflow tract gradient complicated by hypotension
- Mitral regurgitation
- Ventricular arrhythmias
- LV thrombus formation
- LV free wall rupture
- Death (rare, 0–8%)

**DIAGNOSIS**

Because TSC often is indistinguishable from an ACS, it should be treated initially as such:
- Activate emergency medical services or report to emergency department.
- Oxygen, IV access, and ECG monitoring
- Urgent cardiology consultation

**HISTORY**

- In 2/3 of patients, there is exposure to a “trigger event.”
  - Emotional stress: argument, death of family member, divorce, public speaking, and so forth
  - Physiologic stress: acute medical condition such as head trauma, asthma attack, seizure, and so forth
- In 1/3 of patients, there is no identifiable trigger (2).
- Studies suggest preference for time of day, day of the week, and months/season of the year; summer and winter most commonly reported
- Acute onset of dyspnea or chest pain
- Palpitations
- Syncope

**PHYSICAL EXAM**

Exam may be unremarkable or may include any of the following:
- Tachypnea
- Tachycardia
- Hypotension
- Jugular venous distension
- Bibasilar rales
- S\textsubscript{3} gallop
- Systolic ejection murmur due to dynamic LV outflow tract gradient
- Holosystolic murmur of mitral regurgitation

**DIFFERENTIAL DIAGNOSIS**

- Acute ST-segment elevation MI
- Pulmonary embolism
- Myopericarditis
- Pheochromocytoma
- Hypertrophic cardiomyopathy
- Subarachnoid hemorrhage or stroke

**DIAGNOSTIC TESTS & INTERPRETATION**

- ECG should be done urgently and may show the following:
- Diffuse ST-segment elevations
- Diffuse and often dramatic T-wave inversions
- QTc interval prolongation (3)[B]
- Q waves

Laboratory tests typically reveal a mild elevation in cardiac biomarkers such as
- CK (rarely >500 U/mL)
- Troponin I
- B-type natriuretic peptide (BNP)
- Markers of high filling pressures (e.g., BNP) tend to be higher than markers of necrosis
  (e.g., CK, troponin).
- TSC can be distinguished from AMI with 95% specificity using a BNP/TnT ratio ≥1,272
  (sensitivity 52%) (4)[B].

Chest radiograph
- Cardiomegaly
- Pulmonary edema

The InterTAK Diagnostic Score comprises seven parameters (female sex, emotional trigger,
physical trigger, absence of ST-segment depression [except in lead aVR], psychiatric
disorders, neurologic disorders, and QT prolongation) ranked by their diagnostic importance
with a maximum attainable score of 100 points (1).

In patients with non–ST-segment elevation, the InterTAK Diagnostic Score can be considered.
Patients with a low probability (InterTAK score ≤70 points) should undergo coronary
angiography with left ventriculography, whereas in patients with a high score (score ≥ 70),
transthoracic echocardiography should be considered (1).

Echocardiogram
- Reduced LV systolic function
- Abnormal diastolic function, including evidence of increased filling pressures
- Regional wall motion abnormalities in one of the following patterns:
  - Classic or “takotsubo-type” ballooning of the apex with a hypercontractile base
  - “Reverse takotsubo”: apical hypercontractility with basal akinesis
  - “Midventricular” akinesis with apical and basal hypercontractility
  - Focal or localized akinesis of an isolated segment
- Dynamic intracavitary LV gradient
- Mitral regurgitation
- Variable involvement of the RV

Cardiac MRI
- Reduced LV function
- Wall motion abnormalities as described for transthoracic echocardiography
- Absence of delayed hyperenhancement with gadolinium

**Diagnostic Procedures/Other**

The diagnosis of TSC is often challenging because its clinical phenotype may closely resemble
STEMI regarding electrocardiographic abnormalities and biomarkers. Although a widely
established noninvasive tool allowing a rapid and reliable diagnosis of TSC is currently
lacking, coronary angiography with left ventriculography is considered the “gold standard”
diagnostic tool to exclude or confirm TSC.

Coronary angiography
- Nonocclusive CAD
- Rarely, epicardial coronary spasm
- Endothelial dysfunction as measured by fractional flow reserve or TIMI frame counts
- Left-sided heart catheterization: increased LV end-diastolic pressure to a similar degree as AMI
- Ventriculography: wall motion abnormalities as described for transthoracic echocardiography
- Right-sided heart catheterization
  - Increased pulmonary capillary wedge pressure
  - Secondary pulmonary hypertension
  - Increased right ventricular filling pressures
  - Reduced cardiac output or cardiogenic shock (cardiac index <2 and mean arterial pressure [MAP] <60 mm Hg)

**Test Interpretation**
Characteristic pathologic findings of involved myocardium have not been described.

**TREATMENT**
Guidelines regarding TSC management are lacking because no prospective randomized clinical trials have been performed in this patient population. Therapeutic strategies are therefore based on clinical experience and expert consensus (5).

- Activation of emergency medical services
- Advanced cardiac life support therapies as needed
- Oxygen
- IV access
- ECG monitoring

**MEDICATION**
After diagnostic cardiac catheterization, empirical treatment goals are as follows:

- Management of hypotension: differentiation between cardiogenic shock and dynamic LV cavity gradient
- Management of increased filling pressures and congestive states
- Attenuation of sympathetic drive

**First Line**
- There are no evidence-based treatment recommendations for TSC.
- Although β-blockers are of theoretical benefit, their use has not been associated with improved outcomes in observational cohorts (2)[B].
- Due to the potential risk of pause-dependent torsades de pointes, β-blockers should be used cautiously, especially in patients with bradycardia and QTc >500 ms (5).
- If there is evidence of left ventricular systolic dysfunction or pulmonary edema, consider the following:
  - Furosemide: 20 to 40 mg IV/PO BID as needed to reduce LV filling pressures and dyspnea (6)
  - The use of angiotensin-converting enzyme inhibitors or angiotensin receptor blockers was associated with improved survival at 1-year follow-up even after propensity matching (5): Lisinopril 10 to 40 mg/day PO or equivalent or valsartan 80 to 160 mg PO BID has been associated with improved outcomes in observational cohorts (2)[B].
Second Line
Short-term anticoagulation should be considered in patients with severely reduced LV function to prevent LV thrombus formation; unfractionated heparin 80 U/kg IV bolus followed by 18 U/kg/hr IV or Lovenox 1 mg/kg SC BID

ISSUES FOR REFERRAL
All patients with TSC generally should be comanaged with cardiology while inpatient and referred to cardiology as an outpatient.

ADDITIONAL THERAPIES
- Urgent cardiology consultation and consideration of cardiac catheterization
- Hypotension may require the following:
  - Vasopressors (e.g., dopamine or Levophed) if there is no LV outflow tract gradient (6)[C]
  - Phenylephrine and IV fluids to increase afterload in the presence of an LV outflow tract gradient (6)[C]
  - Cardiogenic shock that is not due to an LV outflow tract gradient may require placement of an intra-aortic balloon pump.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admission criteria/initial stabilization
  - 12-lead ECG
  - Chest radiograph
  - Laboratory testing
  - Echocardiography
  - Patients with TSC usually are admitted for observation because the differential diagnosis includes ACS.
- Normal saline infusion to support BP, if necessary, and no evidence of heart failure
- Discharge criteria generally considered after exclusion of ACS and resolution of
  - Congestive state
  - Hypotension
  - Profound impairments of systolic function

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Impairments in systolic function typically resolve in 2 to 3 days but may last as long as 1 month.
- Patients should follow up with cardiology and serial echocardiography to document improved LV function.

PROGNOSIS
- Although TSC has generally been considered a benign disease, contemporary observations show that rates of cardiogenic shock and death are comparable to ACS patients treated according to current guidelines (5).
- Recurrence is rare; it also has been reported in 0–8% of patients.
REFERENCES

SEE ALSO

Algorithm: Chest Pain/Acute Coronary Syndrome

CODES

ICD10
I51.81 Takotsubo syndrome

CLINICAL PEARLS

- TSC is poorly recognized and often regarded as a benign condition. However, it may be associated with severe clinical complications including death, and its prevalence is likely underestimated.
- TSC is a cause of reversible LV dysfunction with a clinical presentation indistinguishable from the ACS, particularly ST-segment elevation MI.
- Echocardiography may strongly suggest the diagnosis.
- Treatment is supportive and should include diuretics and ACE inhibitors in patients with CHF.
TRICHOMONIASIS
Michael J. Arnold, MD

BASICS

DESCRIPTION
- Sexually transmitted urogenital infection caused by a pear-shaped, parasitic protozoan
- Causes vaginitis/urethritis in women, nongonococcal urethritis in men
- In pregnancy, increases risk of preterm labor, preterm premature rupture of membranes, small for gestational age infant, and possibly stillbirth
- Synonym(s): trich; trichomonal urethritis

EPIDEMIOLOGY

Incidence
- The most common curable sexually transmitted infection (STI); in 2008, >275 million new cases worldwide, over half of curable STIs (1)
- Estimated 1.1 million new cases annually in United States
  - 10–25% of vaginal infections
  - In males, up to 17% of nongonococcal urethritis
- Predominant age: middle-aged adults
  - Rare until onset of sexual activity
  - Common in postmenopausal women; age is not protective and long-term carriage is common.

Pediatric Considerations
Rare in prepubertal children; diagnosis should raise concern of sexual abuse.

Prevalence
- 1.8% in United States women age 18 to 59 years
- 0.5% of U.S. men age 18 to 59 years
- Racial disparity demonstrated
  - 8.9% of black women versus 0.8% of other women
  - 4.2% of black men versus 0.03% of other men

ETIOLOGY AND PATHOPHYSIOLOGY
- Trichomonas vaginalis: pear-shaped, flagellated, parasitic protozoan
- Grows best at 35–37°C in anaerobic conditions with pH 5.5 to 6.0
- STI, but nonsexual transmission possible because it can survive several hours in moist environment

Genetics
No known genetic considerations

RISK FACTORS
- Multiple sexual partners
- Unprotected intercourse
- Lower socioeconomic status
Other STIs
- Untreated partner with previous infection
- Use of douching or feminine powders

**GENERAL PREVENTION**
- Use of male or female condoms
- Limiting sexual partners
- Male circumcision may be protective.

**COMMONLY ASSOCIATED CONDITIONS**
- Other STIs, including HIV
- Bacterial vaginosis

**DIAGNOSIS**

**HISTORY**
- Women—up to 80% may be asymptomatic.
  - Yellow-green, malodorous vaginal discharge
  - Vulvovaginal pruritus
  - Dysuria
  - Symptoms often worsen during menses.
- Men—80% are asymptomatic.
  - Dysuria
  - Urethral discharge, often scant
  - Pruritus or burning after intercourse

**PHYSICAL EXAM**
- Women
  - Vaginal erythema
  - Yellow-green, frothy, malodorous vaginal discharge
  - Cervical petechiae (“strawberry cervix”; seen in <5% of patients)
  - Pelvic exams do not improve STI diagnosis (2).
- Men: penile discharge, spontaneous and with expression

**DIFFERENTIAL DIAGNOSIS**
- Women (other vaginitides)
  - Bacterial vaginosis
  - Vaginal candidiasis
  - Chlamydial infection
  - Gonorrheal infection
- Men (other urethritis)
  - Chlamydial infection
  - Gonorrheal infection

**DIAGNOSTIC TESTS & INTERPRETATION**
**Initial Tests (lab, imaging)**
- Wet mounts of vaginal or urethral discharge: direct visualization of motile trichomons; most
common because inexpensive and available
- Sensitivity: 60–70%; declines rapidly within 1 hour from collection
- Specificity: 99.8%

Culture: sensitivity >95%, specificity >99%; takes 4 to 7 days for growth

Nucleic acid amplification test (NAAT)
- Gold standard for diagnosis (3)
- Sensitivity and specificity 95–99% (3)
- Vaginal, endocervical, or urine specimens
  - British analysis shows that combined NAAT for Trichomonas, gonorrhea, Chlamydia, and Mycoplasma genitalium most cost-effective (3)[B].

Antigen detection
- ELISA and direct fluorescent antibody tests: sensitivity of 80–90%
- Limited clinical availability

Follow-Up Tests & Special Considerations
Detection on cervical Papanicolaou smear
- Treat because highly specific (97–99%)
- Not effective for Trichomonas screening—sensitivity as low as 60%

Diagnostic Procedures/Other
In males, urethral meatal swab increases Trichomonas detection rate by 4 times over urine.

TREATMENT
- Symptomatic individuals require treatment.
- Sexual partners should be treated presumptively.
- Patients should abstain from sexual intercourse during treatment and until they are asymptomatic.

GENERAL MEASURES
The nitroimidazole class is only known effective antimicrobial treatment. If metronidazole resistance is suspected, use tinidazole (4)[A].

MEDICATION
First Line
- Metronidazole: 2 g PO, 1 dose (4)[A]
  - FDA pregnancy risk Category B
  - Cure rate: 84–98%
- Tinidazole: 2 g PO, 1 dose (4)[A]
  - FDA pregnancy risk Category C
  - Abstain from breastfeeding during treatment and for 3 days after the dose.
  - More expensive
  - Reaches higher levels in genitourinary tract
  - Cure rate: 92–100%

Second Line
- Metronidazole: 500 mg PO BID for 7 days
– Number needed to treat of 13 for negative test of cure versus single dose metronidazole (5) [B]
– Considered first line in HIV-positive individuals
– Can dose with metronidazole or tinidazole 2 g daily for 7 days if infection persists
– Consider IV dosing of metronidazole based on case report demonstrating cure after multiple failed oral regimens.

**Pregnancy Considerations**
Metronidazole is effective for trichomoniasis infection during pregnancy but may increase the risk of preterm and low-birth-weight babies.
- Studies showed risk in patients receiving 4 times the standard dosing.
- Trichomoniasis is also associated with prematurity.

**ISSUES FOR REFERRAL**
- Multidrug-resistant organism
- Patient allergy to metronidazole: Desensitization to metronidazole is recommended.

**ADDITIONAL THERAPIES**
- Limited clinical trials assessing effectiveness of alternative therapies
- Intravaginal metronidazole gel is not effective (6)[B].
- Suggested alternative therapies based on case reports (6)[C]
  - Paromomycin 6.25% cream
  - Povidone-iodine douche
  - Boric acid intravaginally
  - Furazolidone intravaginally

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
See “Additional Therapies.”

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- If symptoms persist after initial treatment, repeat wet mount or other testing.
- Retest women for T. vaginalis recommended within 3 months of treatment; data insufficient for retesting men (5)
- HIV-positive patients should be screened for Trichomonas at time of HIV diagnosis and at least annually (5).

**DIET**
Abstain from alcohol during treatment and for 24 hours following last dose of metronidazole or 48 to 72 hours following last dose of tinidazole due to disulfiram-like reaction.

**PATIENT EDUCATION**
Educate about the sexually transmitted aspect.
- Advise patient to notify sexual partner to be treated.
- Discuss STI prevention—condom use can prevent recurrence.
- Abstain from intercourse while undergoing treatment; use condoms if abstention is not
feasible.
- Avoid alcohol during treatment with metronidazole or tinidazole.

PROGNOSIS
- Excellent
- Usually eliminated after one course of antibiotics

COMPLICATIONS
Pregnancy Considerations
Linked to low birth weight, preterm premature rupture of membranes, and preterm birth; associations with infertility, but not proven

REFERENCES

ADDITIONAL READING

CODES

ICD10

- A59.9 Trichomoniasis, unspecified
- A59.03 Trichomonal cystitis and urethritis
- A59.01 Trichomonal vulvovaginitis

CLINICAL PEARLS

- Both partners need to be treated for trichomoniasis.
- Retest women within 3 months of treatment.
- Avoid alcohol during treatment.
- Treatment in pregnancy does not reduce risk of adverse pregnancy outcomes.
- Annual screening recommended for HIV-positive patients
- Not a nationally notifiable condition
TRIGEMINAL NEURALGIA
Noah M. Rosenberg, MD, MBA

BASICS
DESCRIPTION
● A painful disorder of the sensory nucleus of the trigeminal nerve (cranial nerve [CN] V) that produces episodic, paroxysmal, severe, lancinating facial pain lasting seconds to minutes in the distribution of ≥1 divisions of the nerve
● Often precipitated by stimulation of well-defined, ipsilateral trigger zones: usually perioral, perinasal, and occasionally intraoral (e.g., by washing, shaving)
● System(s) affected: nervous
● Synonym(s): tic douloureux; Fothergill neuralgia; trifacial neuralgia; prosopalgia

EPIDEMIOLOGY
Incidence
● Women: 5.9/100,000 per year
● Men: 3.4/100,000 per year
● >70 years of age: ~25.6/100,000 per year
● Predominant age:
  – >50 years; incidence increases with age.
  – Rare: <35 years of age (Consider another primary disease; see “Etiology and Pathophysiology.”)
● Predominant sex: female > male (~2:1)

Prevalence
16/100,000

Pediatric Considerations
Unusual during childhood

Pregnancy Considerations
Teratogenicity limits therapy for 1st and 2nd trimesters.

ETIOLOGY AND PATHOPHYSIOLOGY
● Demyelination around the compression site seems to be the mechanism by which compression of nerves leads to symptoms.
● Demyelinated lesions may set up an ectopic impulse generation causing erratic responses: hyperexcitability of damaged nerves and transmission of action potentials along adjacent, undamaged, and unstimulated sensory fibers.
● Compression of trigeminal nerve by anomalous arteries or veins of posterior fossa, compressing trigeminal root
● Etiologic classification:
  – Idiopathic (classic)
  – Secondary: cerebellopontine angle tumors (e.g., meningioma); tumors of CN V (e.g., neuroma, vascular malformations), trauma, demyelinating disease (e.g., multiple sclerosis
RISK FACTORS
Unknown

COMMONLY ASSOCIATED CONDITIONS
- Sjögren syndrome; rheumatoid arthritis
- Chronic meningitis
- Acute polyneuropathy
- MS
- Hemifacial spasm
- Charcot-Marie-Tooth neuropathy
- Glossopharyngeal neuralgia

DIAGNOSIS

HISTORY
Paroxysms of pain in the distribution of the trigeminal nerve. The trigeminal nerve has three branches and innervates the entire side of the face. They are known as ophthalmologic (V1), maxillary (V2), and mandibular (V3) branches. Patients typically experience pain in the V2 and V3 dermatomes.

PHYSICAL EXAM
All exam findings typically are negative due to the paroxysmal nature of the disorder.

DIFFERENTIAL DIAGNOSIS
- Other forms of neuralgia usually have sensory loss. Presence of sensory loss nearly excludes the diagnosis of trigeminal neuralgia (TN) (if younger patient, frequently MS).
- Neoplasia in cerebellopontine angle
- Vascular malformation of brainstem
- Demyelinating lesion (MS is diagnosed in 2–4% of patients with TN.)
- Vascular insult
- Migraine, cluster headache
- Giant cell arteritis
- Postherpetic neuralgia
- Chronic meningitis
- Acute polyneuropathy
- Atypical odontalgia
- SUNCT syndrome (short-lasting, unilateral neuralgiform pain with conjunctival injection and tearing)

DIAGNOSTIC TESTS & INTERPRETATION
- The International Headache Society diagnostic criteria for classic TN are as follows:
  - Paroxysmal attacks of pain lasting from a fraction of 1 second to 2 minutes, affecting ≥1 divisions of the trigeminal nerve
  - Pain has at least an intense, sharp, superficial, or stabbing characteristic or is precipitated from trigger areas or by trigger factors.
– Attacks are stereotyped in the individual patient.
– No clinically evident neurologic deficit found
– Not attributed to another disorder

• Secondary TN is characterized by pain that is indistinguishable from classic TN but is caused by a demonstrable structural lesion other than vascular compression.
  – Indicated in all first-time-presenting patients to rule out secondary causes
• MRI versus CT scan: MRI, with and without contrast, offers more detailed imaging and is preferred, if not contraindicated.
• Routine head imaging identifies structural causes in up to 15% of patients.
• No positive findings are significantly correlated with diagnosis.

**Test Interpretation**

• Trigeminal nerve: inflammatory changes, demyelination, and degenerative changes
• Trigeminal ganglion: hypermyelination and microneuromata

**TREATMENT**

**GENERAL MEASURES**

• Outpatient
• Drug treatment is first line.
• Invasive procedures are reserved for patients who cannot tolerate, fail to respond to, or relapse after chronic drug treatment.
• Avoid stimulation (e.g., air, heat, cold) of trigger zones, including lips, cheeks, and gums.

**MEDICATION**

**First Line**

• Carbamazepine (Tegretol) (1)[A]: Start at 100 to 200 mg BID; effective dose usually 200 mg QID; max dose 1,200 mg/day:
  – 70–90% of patients respond initially (number needed to treat \[NNT\] = 1.9) (1)[A].
  – By 3 years, 30% are no longer helped.
  – Most common side effect: sedation
• Contraindications: concurrent use of monoamine oxidase inhibitors (MAOIs)
• Precautions: caution in the presence of liver disease
• Significant possible medication interactions: macrolide antibiotics, oral anticoagulants, anticonvulsants, tricyclics, oral contraceptives, steroids, digitalis, isoniazid, MAOIs, methyprylon, nabilone, nizatidine, other H₂ blockers, phenytoin, propoxyphene, benzodiazepines, and calcium channel blockers
• Oxcarbazepine (Trileptal): Start at 150 to 300 mg BID; effective dose usually 375 mg BID; max dose 1,200 mg/day:
  – Efficacy similar to carbamazepine
  – Faster, with less drowsiness and fewer drug interactions than carbamazepine
  – May cause hyponatremia
  – Most common side effect: sedation

**Second Line**

• Antiepileptic drugs: insufficient evidence from randomized controlled trials to show
**Phenytoin (Dilantin):** 300 to 400 mg/day (synergistic with carbamazepine):
- Potent P450 inducer (enhanced metabolism of many drugs)
- Various CNS side effects (sedation, ataxia)

**Baclofen (Lioresal):** 10 to 80 mg/day; start at 5 to 10 mg TID with food (as an adjunct to phenytoin or carbamazepine); side effects: drowsiness, weakness, nausea, vomiting

**Gabapentin (Neurontin):** Start at 100 mg TID or 300 mg at bedtime; can increase dose up to 300 to 600 mg TID–QID; can be used as monotherapy or in combination with other medications

**Lamotrigine:** Titrate up to 200 mg BID over weeks; side effect: 10% experience rash.

**Antidepressants,** including amitriptyline, fluoxetine, trazodone:
- Used especially with anticonvulsants
- Particularly effective for atypical forms of TN

**Clonazepam (Klonopin)** frequently causes drowsiness and ataxia.

**Sumatriptan (Imitrex)** 3 mg subcutaneous (SC) reduces acute symptoms and may be helpful after failure of conventional medical therapy.

**Capsaicin cream topically**

**Botulinum toxin injection into zygomatic arch**

**Valproic acid (Depakene, Depakote)**

---

**ISSUES FOR REFERRAL**
Initial treatment failure or positive findings on imaging studies

**ADDITIONAL THERAPIES**

**Radiotherapy**

Stereotactic radiosurgery, such as Gamma Knife radiosurgery, has been shown to be effective after drug failure:
- Produces lesions with focused Gamma Knife radiation
- Therapy aimed at the proximal trigeminal root
- Minimal clinically effective dose: 70 Gy
- ~78–94% of patients achieve complete relief after 3 years; by 7 years, ~65–90% maintain complete relief (3)[B].
  - Most common side effect: sensory disturbance (facial numbness)
  - Failure rates are higher in patients with past TN-related invasive procedures.

**Surgery/Other Procedures**

**Microvascular decompression of CN V at its entrance to (or exit from) brainstem:**
- 98% of patients achieve initial pain relief; by 20 months, 86% maintain complete relief (NNT = 2) (4)[B].
  - Surgical mortality across studies was 0.3–0.4%.
  - Most common side effect: transient facial numbness and diplopia, headache, nausea, vomiting
  - Pain relief after procedure strongly correlates with the type of TN pain: Type 1 (shock-like pain) results in better outcomes than type 2 (aching pain between paroxysms).

**Peripheral nerve ablation (multiple methods):**
- Higher rates of failure and facial numbness than decompression surgery
- Radiofrequency thermocoagulation
Neurectomy
Cryotherapy: high relapse rate
Partial sensory rhizotomy

- 4% tetracaine dissolved in 0.5% bupivacaine nerve block (only a few case reports to date; ropivacaine)
- Alcohol block or glycerol injection into trigeminal cistern: unpredictable side effects (dysesthesia and anesthesia dolorosa); temporary relief
- Peripheral block or section of CN V proximal to gasserian ganglion
- Balloon compression of gasserian ganglion
- Evidence supporting destructive procedures for benign pain conditions remains limited (5)[A].

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Acupuncture, moxibustion (herb): weak evidence for efficacy (6)[B]

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Regular outpatient follow-up to monitor symptoms and therapeutic failure

**Patient Monitoring**
- Carbamazepine and/or phenytoin serum levels
- If carbamazepine is prescribed: CBC and platelets at baseline, then weekly for a month, then monthly for 4 months, and then every 6 to 12 months if dose is stable (Regimens for monitoring vary.)
- Reduce drugs after 4 to 6 weeks to determine whether condition is in remission; resume at previous dose if pain recurs. Withdraw drugs slowly after several months, again to check for remission or if lower dose of drugs can be tolerated.

**DIET**
No special diet

**PATIENT EDUCATION**
- Instruct patient regarding medication dosage and side effects, risk-to-benefit ratios of surgery, or radiation therapy.
- Support organizations:
  - Facial Pain Association (formerly the Trigeminal Neuralgia Association): www.fpa-support.org
  - Living with Facial Pain: www.livingwithfacialpain.org

**PROGNOSIS**
- 50–60% eventually fail pharmacologic treatment.
- After having microvascular decompression surgery, most patients wish they had undergone the procedure sooner.
- Of those, relapse is seen in ~50% of stereotactic radiosurgeries and ~27% of surgical microvascular decompressions.

**COMPLICATIONS**
- Mental and physical sluggishness; dizziness with carbamazepine
- Paresthesias and corneal reflex loss with stereotactic radiosurgery
- Surgical mortality and morbidity associated with microvascular decompression

REFERENCES

ADDITIONAL READING

CODES
ICD10
- G50.0 Trigeminal neuralgia
- B02.22 Postherpetic trigeminal neuralgia

CLINICAL PEARLS
- Patients with TN typically have a normal physical exam.
- The long-term efficacy of pharmacotherapy for TN is 40–50%.
- If pharmacotherapy fails, stereotactic radiosurgery or surgical microvascular decompression often is successful.
TRIGGER FINGER (DIGITAL STENOSING TENOSYNOVITIS)
Jill N. Tirabassi, MD

BASICS

DESCRIPTION
A clicking, snapping, or locking of a finger/thumb with extension movement (after flexion) ± associated pain

EPIDEMIOLOGY

Incidence
- Adult population: 28/100,000/year
  - Rare in children
- 4 times increased risk in diabetics (1)[B]
- Thumb is predominant digit.
- Predominant age
  - Adult form typically presents in the 5th and 6th decades of life.
- Predominant sex
  - Children: female = male
  - Adults: female > male (6:1)

Prevalence
Lifetime prevalence in the general population is 2.6%.

Pediatric Considerations
- Surgery is often more complicated for children with a trigger finger (as opposed to a trigger thumb).
- Release of the A1 pulley alone is often insufficient; other procedures may be necessary.

ETIOLOGY AND PATHOPHYSIOLOGY

- Narrowing around the A1 pulley from inflammation, protein deposition, or thickening of the tendon itself. Prolonged inflammation leads to fibrocartilaginous metaplasia of the tendon sheath.
- If flexor tendon becomes nodular, the triggering phenomenon is worse because the nodule has difficulty passing under the A1 pulley.
- Because intrinsic flexor muscles are stronger than extensors, the finger can stick in the flexed position.
- No clear association with repetitive movements

RISK FACTORS
- Diabetes mellitus
- Rheumatoid arthritis
- Hypothyroidism
- Mucopolysaccharide disorders
- Amyloidosis
GENERAL PREVENTION
Most cases are idiopathic, and no known prevention exists; no clear association with repetitive movements

COMMONLY ASSOCIATED CONDITIONS
- De Quervain tenosynovitis
- Carpal tunnel syndrome
- Dupuytren contracture
- Diabetes mellitus
- Rheumatoid arthritis
- Hypothyroidism
- Amyloidosis

DIAGNOSIS
Diagnosis is based on clinical presentation.

HISTORY
Clicking, catching, snapping, or locking of a digit while attempting to extend; with or without associated pain; usual progression is painless clicking, then painful triggering then flexed, locked digit

PHYSICAL EXAM
- A palpable nodule may be present.
- Snapping/locking may be present, but neither is necessary for the diagnosis.
- Tenderness to palpation is variable.

DIAGNOSTIC TESTS & INTERPRETATION
Test Interpretation
On ultrasound or MRI:
- Thickening of the A1 pulley with fibrocartilaginous metaplasia
- Thickening/nodule formation of flexor tendon

TREATMENT
GENERAL MEASURES
- Activity modification can be helpful in early disease (2)[C].
- Most recommend attempting steroid injection prior to surgery (2)[C].
- Splinting may be more effective in preventing recurrence than initial treatment choice (3)[B].
- Splinting the metacarpophalangeal (MCP) joint at 10 to 15 degrees of flexion for 6 weeks with the distal joints free to move:
  - Splinting is more effective for fingers than thumbs (70% vs. 50%).
  - Splinting is less effective with severe symptoms, symptoms >6 months, or if multiple digits are involved (1)[B].
- Injection of long-acting corticosteroid may provide symptom relief. Subsequent injections are less likely to help (1)[B].
- Surgery often successful for patients unresponsive to splinting/corticosteroid injections or who suffered recurrence (2)[B]

**MEDICATION**

**First Line**
- Steroid injection of the tendon sheath/surrounding SC tissue has 57–90% success rate.
- Triamcinolone appears more effective than dexamethasone (2)[B].
- Injection in surrounding tissues is as efficacious as injecting into the tendon sheath (1,2)[B].
- Injection into the palmar surface at the midproximal phalanx is associated with less pain than injection of tendon sheath at MCP joint (4)[B].
- Corticosteroid injection has higher success rate than splinting (3)[B].

**Second Line**
- Oral NSAIDs may reduce pain and discomfort but have not been shown to alter underlying disease. NSAIDs do not reduce symptoms of snapping/locking.
- Injection with diclofenac may be an alternative to corticosteroid for patients with diabetes mellitus if increase in blood sugar is a concern (2)[A].
- Corticosteroids are more effective than diclofenac during the first 3 weeks postinjection. Efficacy is similar to other modalities by 3 months postinjection (2)[B].

**ISSUES FOR REFERRAL**
Refer to a hand surgeon for A1 pulley release if the patient is not responding to conservative treatment.

**ADDITIONAL THERAPIES**
Physiotherapy is helpful, particularly in children.

**SURGERY/OTHER PROCEDURES**
- Surgical release can be done as an open procedure or percutaneously.
- No apparent differences in success or rates of complications between surgical approaches (5)[A]
- Surgery has lower rate of recurrence than corticosteroid injection but has disadvantage of being more painful initially (5)[A].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Day surgery for trigger finger release
- Discharge criteria: absence of complications

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Follow-up is needed only if symptoms persist or if complications develop after surgery.
- Splinting of the affected digit to minimize flexion/extension of the MCP joint helps symptom resolution (1)[B].

**PROGNOSIS**
Prognosis is excellent with conservative treatment or surgical intervention. Recurrence following
corticosteroid injection is more likely for patients with type 1 diabetes mellitus, younger patients, involvement of multiple digits, and history of other upper extremity tendinopathies (2)[B].

COMPLICATIONS

- Diabetic patients may have increased blood sugar levels for up to 5 days following steroid injection.
- Other minor injection complications include skin depigmentation and fat necrosis; tendon attrition or rupture is rare.
- Complications from surgery include infection, bleeding, digital nerve injury, persistent pain, and loss of range of motion of the affected finger. The rate of major complications is low (3%). The rate of minor complications (including loss of range of motion) is higher (up to 28%).
- Another surgical complication, injury to the A2 pulley, may result in bowstringing (bulging of the flexor tendon in the palm with flexion) and pain.

REFERENCES

ADDITIONAL READING

CODES

ICD10

- M65.30 Trigger finger, unspecified finger
● M65.319 Trigger thumb, unspecified thumb
● M65.329 Trigger finger, unspecified index finger

CLINICAL PEARLS

● Trigger finger is caused by narrowing of the A1 flexor tendon pulley.
● Diagnosis is based on clinical presentation.
● Initial conservative treatment can include splinting or corticosteroid injection.
● Long-acting corticosteroid injections are effective for treatment of trigger finger but have high recurrence rate than surgery.
● Open and percutaneous surgical release have high success rates for patients not responsive to splinting or injections.
TROCHANTERIC BURSITIS (GREATER TROCHANTERIC PAIN SYNDROME)

David W. Kruse, MD  ●  Joshua Wathen, MD

BASICS

Trochanteric bursitis is the historical term referring to lateral hip pain and tenderness over the greater trochanter. Because many patients lack an inflammatory process within the trochanteric bursa, this condition has been more recently referred to as greater trochanteric pain syndrome (GTPS) (1).

DESCRIPTION

● Bursae are fluid-filled sacs found primarily at tendon attachment sites with bony protuberances:
  – Multiple bursae are in the area of the greater trochanter of the femur.
  – These bursae are associated with the tendons of the gluteus muscles, iliotibial band (ITB), and tensor fasciae latae.
  – The subgluteus maximus bursa is implicated most commonly in lateral hip pain (1).

● Other structures of the lateral hip include the following:
  – ITB, tensor fasciae latae, gluteus maximus tendon, gluteus medius tendon, gluteus minimus tendon, quadratus femoris muscle, vastus lateralis tendon, piriformis tendon

● Bursitis refers to bursal inflammation.

● Tendinopathy refers to any abnormality of a tendon, inflammatory or degenerative. Enthesopathy refers to abnormalities of the zones of attachment of ligaments and tendons to bones.

EPIDEMIOLOGY

Incidence

● 1.8/1,000 persons/year

● Peak incidence in 4th to 6th decades

Prevalence

● Predominant sex: female > male

● More common in running and contact athletes (e.g., football, rugby, soccer)

ETIOLOGY AND PATHOPHYSIOLOGY

● Acute: Abnormal gait or poor muscle flexibility and strength imbalances lead to bursal friction and secondary inflammation.
  – Tendon overuse and inflammation
  – Direct trauma from contact or frequently lying with body weight on hip can cause an inflammatory response (“hip pointer”) as well.

● Chronic
  – Fibrosis and thickening of bursal sac due to chronic inflammatory process
  – Tendinopathy due to chronic overuse and degeneration: gluteus medius and minimus most commonly involved (1)
Genetics
No known genetic factors

RISK FACTORS
Multiple factors have been implicated (1):
- Female gender
- Obesity
- Tight hip musculature (including ITB)
- Direct trauma
- Total hip arthroplasty
- Abnormal gait or pelvic architecture
  - Leg length discrepancy
  - Sacroiliac (SI) joint dysfunction
  - Knee or hip osteoarthritis
  - Abnormal foot mechanics (e.g., pes planus, overpronation)
  - Neuromuscular disorder: Trendelenburg gait

GENERAL PREVENTION
- Maintain ITB, hip, and lower back flexibility and strength.
- Avoid direct trauma (use of appropriate padding in contact sports).
- Avoid prolonged running on banked or crowned surfaces.
- Wear appropriate shoes.
- Appropriate bedding and sleeping surface
- Maintain appropriate body weight loss.

COMMONLY ASSOCIATED CONDITIONS
- Biomechanical factors (1)
  - Tight ITBs, leg length discrepancy, SI joint dysfunction, pes planus
  - Width of greater trochanters greater than width of iliac wings
- Other associated pathology (1):
  - Low back pain
  - Knee and hip osteoarthritis
  - Obesity

DIAGNOSIS

HISTORY
General history (1)
- Pain localized to the lateral hip or buttock
- Pain may radiate to groin or lateral thigh (pseudoradiculopathy).
- Pain exacerbated by:
  - Prolonged walking or standing
  - Rising after prolonged sitting
  - Sitting with legs crossed
  - Lying on affected side
- Other historical features:
– Direct trauma to affected hip
– Chronic low back pain
– Chronic leg/knee/ankle/hip pain
– Recent increase in running distance or intensity
– Change in running surfaces

PHYSICAL EXAM

● Observe gait.
● Point tenderness with direct palpation over the lateral hip is characteristic of GTPS (1)[B].
● Other exam features have lower sensitivity (1)[B]:
  – Pain with extremes of passive rotation, abduction, or adduction
  – Pain with resisted hip abduction and external or internal rotation
  – Trendelenburg sign
● Other tests to rule out associated conditions:
  – Patrick-FABERE (flexion, abduction, external rotation, extension) test for SI joint dysfunction
  – Ober test for ITB pathology
  – Flexion and extension of hip for osteoarthritis
  – Leg length measurement
  – Foot inspection for pes planus or overpronation
  – Lower extremity neurologic assessment for lumbar radiculopathy or neuromuscular disorders
  – Hip lag sign (2)

DIFFERENTIAL DIAGNOSIS

● ITB syndrome
● Piriformis syndrome
● Osteoarthritis or avascular necrosis of the hip
● Lumbosacral osteoarthritis/disc disease with nerve root compression
● Fracture or contusion of the hip or pelvis—particularly in setting of trauma
● Stress reaction/fracture of femoral neck—particularly in female runners
● Septic bursitis/arthritis

DIAGNOSTIC TESTS & INTERPRETATION

No routine lab testing is recommended.

Initial Tests (lab, imaging)

● Diagnosis can be made by history and exam (3).
● If imaging is ordered:
  – Ultrasound can aid in diagnosis and guide aspiration and/or injection.
  – Anteroposterior and frog-leg views of affected hip to rule out specific bony pathology (e.g., osteoarthritis, stress fracture)
  – Consider lumbar spine radiographs if back pain is thought to be a contributing factor.
  – Magnetic resonance imaging (MRI) is image of choice in recalcitrant pain or to formally exclude stress fracture.

Follow-Up Tests & Special Considerations

● If there is a concern for a septic bursitis, then aspiration or incision and drainage may be
Advanced imaging rarely necessary; detection of abnormalities on MRI is a poor predictor of GTPS (4)[B].

**TREATMENT**

**GENERAL MEASURES**
- Physical therapy to address underlying dysfunction and rebuild atrophic muscle
- Correct pelvic/hip instability.
- Correct lower limb biomechanics.
- Low-impact conditioning and aquatic therapy
- Gait training
- Weight loss (if applicable)
- Minimize aggravating activities such as prolonged walking or standing.
- Avoid lying on affected side.
- Runners
  - May need to decrease distance and/or intensity of runs during treatment. Some need to stop running. Amount of time is case specific but may range from 2 to 4 weeks.
  - Avoid banked tracks or roads with excessive tilt.

**MEDICATION**

**First Line**
- NSAIDs (1)[B]: Treat for 2 to 4 weeks.
  - Naproxen: 500 mg PO BID
  - Ibuprofen: 800 mg PO TID
- Corticosteroid injection is effective for pain relief (5)[C] and can be considered first-line therapy for selected cases:
  - Dexamethasone: 4 mg/mL or
  - Kenalog: 40 mg/mL, use 1 to 2 mL
  - Consider adding a local anesthetic (short- and/or long-acting) for more immediate pain relief.
  - Can be repeated with similar effect if original treatment showed a strong response
  - Goal is pain relief.
  - Corticosteroid injections may not be effective for certain cases (6). A non-inflammatory cause, such as a chronic tendinopathy or referred pain, should be considered and further explored in these cases.

**ISSUES FOR REFERRAL**
- Septic bursitis
- Recalcitrant bursitis

**ADDITIONAL THERAPIES**
- Ice
  - Low-energy shock wave therapy has been shown to be superior to other nonoperative modalities (7).
- Focus on achieving flexibility of hip musculature, particularly the ITB.
Address contributing factors:
- Low back flexibility
- If leg length discrepancy, consider heel lift.
- If pes planus or overpronation, consider arch supports or custom orthotics.

SURGERY/OTHER PROCEDURES
- Surgery rare but effective in refractory cases
  - If surgery is indicated, potential options include:
    - Arthroscopic bursectomy
    - ITB release
    - Gluteus medius tendon repair

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Acupuncture
- Prolotherapy
- Growth factor injection techniques
- Platelet-rich plasma injection

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
4 weeks posttreatment, sooner if significant worsening

PATIENT EDUCATION
- Maintain hip musculature flexibility, including ITB.
- Correct issues that may cause abnormal gait:
  - Low back pain
  - Knee pain
  - Leg length discrepancy (heel lift)
  - Foot mechanics (orthotics)
- Gradual return to physical activity

PROGNOSIS
Depends on chronicity and recurrence, with more acute cases having an excellent prognosis

COMPLICATIONS
Bursal thickening and fibrosis

REFERENCES

ADDITIONAL READING

CODES
- ICD10
  - M70.60 Trochanteric bursitis, unspecified hip
  - M70.62 Trochanteric bursitis, left hip
  - M70.61 Trochanteric bursitis, right hip

CLINICAL PEARLS
- Patients with GTPS often present with an inability to lie on the affected side.
- Femoral neck stress fractures are a do-not-miss diagnosis, particularly in young female runners.
- Corticosteroid injection helps as an initial therapy, particularly for pain relief to allow for aggressive physical therapy.
- Physical therapy is treatment mainstay for correcting biomechanical imbalances and restoring proper function.
TUBERCULOSIS
Michael C. Stefanowicz, DO

BASICS

DESCRIPTION

- Active tuberculosis (TB)
  - Primary infection or reactivation of latent infection
  - Without preventive therapy, affects 10% of infected individuals
  - Risk increases with immunosuppression: highest risk first 2 years after infection.
    Reactivation risk increases with comorbid disease (e.g., HIV, diabetes).
  - Well-described forms: pulmonary (85% of cases), miliary (disseminated), meningeal, abdominal, lymphadenitis (scrofula)
- Usually acquired by inhalation of airborne bacilli from an individual with active TB. Bacilli multiply in alveoli and spread via macrophages, lymphatics, and blood. Three possible outcomes:
  - Eradication: Tissue hypersensitivity halts infection within 10 weeks.
  - Primary TB
  - Latent TB (See “Tuberculosis, Latent (LTBI).”)

Pediatric Considerations

- Children more commonly have severe disease, higher risk, and faster rate of progression to disease.
- Most children with pulmonary TB are asymptomatic.
- Pediatric TB treatment should be directly observed (directly observed therapy [DOT]) using four drugs.

EPIDEMIOLOGY

Incidence

- Worldwide (2017): 10.4 million (133 cases per 100,000) population; highest incidence in Asia and Africa. Higher burden countries have approximately 150 cases/100,000 population
- United States (2018): 9,093 (2.8/100,000); incidence in foreign-born 14 times that of U.S.-born persons. Incidence in the U.S. declined by 1.3% from 2017–2018. California, Florida, Texas, and New York account for half of all new TB cases in the US.

Prevalence

- Mortality
  - Worldwide (2017): 1.6 million deaths due to TB. Second leading infectious cause of death worldwide

ETIOLOGY AND PATHOPHYSIOLOGY

- Mycobacterium tuberculosis, Mycobacterium bovis, or Mycobacterium africanum are causative organisms.
- Spread by aerosol droplets (5–10 micron diameter) and reach alveolar space. Alveolar
macrophages ingest and migrate.

- Cell-mediated response by activated T lymphocytes and macrophages forms a granuloma (“tubercle”) that limits bacillary replication. If bacterial replication continues, the tubercle grows with spread to regional lymph nodes. An expanding tubercle within the lung parenchyma combined with regional lymph node enlargement is called a Ranke complex.
- As the infection is contained, destruction of the macrophages produces early “solid necrosis.” In 2 to 3 weeks, “caseous necrosis” develops and LTBI ensues. In the immunocompetent, granuloma undergoes “fibrosis” and calcification. In the immunocompromised, primary progressive TB develops. Cavitary lesions may form. Necrotic lesions may rupture into bronchioles with resulting aerosolization of tuberculous bacilli.

RISK FACTORS

- For infection: homeless, correctional facilities, close contact with infected person, ethnic minorities born in endemic areas of the world living in areas with high incidence of active TB, health care workers; medically underserved, low income, substance abuse
- For development of disease once infected: chronic renal failure; lymphoma; silicosis; diabetes mellitus; cancer of head, neck, or lung; children <5 years of age; malnutrition; systemic corticosteroids; HIV; immunosuppressive drugs; IV drug abuse, alcohol abuse, cigarette smokers; <2 years since infection with M. tuberculosis; history of gastrectomy or jejunal bypass; <90% of ideal body weight

GENERAL PREVENTION

- Screen for and treat LTBI. Report active TB to health department; test and treat all close contacts.
- Bacillus Calmette-Guérin (BCG) vaccine: relatively ineffective in adults. In children, live attenuated M. bovis prevents 50% of pulmonary disease and 80% of meningitis and miliary disease. More commonly used in endemic countries. In the United States BCG is generally not recommended and very rarely used for high-risk children with negative PPD and ongoing exposure from parents or close contacts.

COMMONLY ASSOCIATED CONDITIONS

Immunosuppression; HIV coinfection; malignancy

DIAGNOSIS

HISTORY

- Known exposure to individual with active TB
- Immunosuppression
- Tobacco use; recreational drug use
- Signs and symptoms
  - General: fever, night sweats, unintentional weight loss, malaise, painless lymph node swelling, arthralgias
  - Pulmonary TB: unexplained cough >2 to 3 weeks, hemoptysis, pleuritic chest pain
  - Abdominal TB: acutely as surgical abdomen; chronic abdominal TB varies (vague abdominal symptoms, abdominal mass, “doughy” abdomen).
  - Meningitis: See “Tuberculosis, CNS.”
  - Miliary: See “Tuberculosis, Miliary.”
PHYSICAL EXAM
- Often entirely normal. Specific findings depend on organs involved: hepatosplenomegaly, adenopathy, rales; poor weight gain in children
- Late findings: renal, bone, or CNS disease

DIFFERENTIAL DIAGNOSIS
- Pulmonary TB: pneumonia (bacterial, fungal, atypical), malignancy, actinomycosis, coccidiomycosis, Wegener, noninfectious granulomatous diseases (e.g., sarcoidosis), tularemia
- Extrapulmonary TB: other mycobacterial infections, syphilis, cat-scratch disease, leishmaniasis, erythema nodosum, rheumatologic disease, erythema induratum

DIAGNOSTIC TESTS & INTERPRETATION
To determine immune response to mycobacterium
- Tuberculin skin test (TST) (e.g., PPD): 5 U (0.1 mL) intermediate-strength intradermal injection into volar forearm. Measure induration at 48 to 72 hours:
  - PPD positive if induration
    o >5 mm and HIV infection, recent TB contact, immunosuppressed, disease on x-ray
    o >10 mm and age <4 years or other risk factors
    o >15 mm and age >4 years and no risk factors
  - Two-step test, 1 to 3 weeks apart: no recent PPD, age >55 years, nursing home resident, prison inmate, or health care worker
  - Context of PPD results:
    o False positive: BCG (unreliable, should not affect decision to treat)
    o False negative: HIV, steroids, gastrectomy, alcoholism, renal failure, sarcoidosis, recent viral vaccination, malnutrition, hematologic or lymphoreticular disorder, very recent exposure
    o If positive once, no need to repeat
- Interferon-γ release assays (IGRAs) measure interferon release after stimulation in vitro by M. tuberculosis antigens:
  - With very few exceptions, do not cross-react with BCG and most nontuberculous mycobacteria
    o IGRA preferred for persons who have had BCG (vaccine or for cancer therapy) and those unlikely to return for TST interpretation.
    o TST preferred if age <5 years. The American Academy of Pediatrics now endorses IGRA in BCG-vaccinated children ≥2 years of age.
    o Either TST or IGRA may be used as periodic screening for persons in high-risk occupations and for recent contacts of persons with known or suspected active TB.
    o May be falsely negative in severely immunosuppressed patients (AIDS, chemotherapy)
- TST and IGRA cannot discern LTBI from active TB.
- Updated Centers for Disease Control (CDC) guidelines no longer recommend annual LTBI screening of healthcare workers without elevated risk profile once baseline testing complete (1).

Initial Tests (lab, imaging)
Active TB
- Three sputum samples (8 to 24 hours apart, at least one early morning sample) for acid-fast bacilli (AFB) stain and mycobacterial culture by aerosol induction, gastric aspirate (children),
or bronchoalveolar lavage
- Positive AFB: Treat immediately; culture and sensitivity guide treatment.
- Nucleic acid amplification test (NAAT): Use as an adjunct to culture and AFB smear. Positive result supports presumptive diagnosis of TB while culture pending. Negative NAAT does not rule out TB.
- Chest radiograph
  - Primary TB: infiltrate with or without atelectasis, effusion, or adenopathy. Ghon lesion: calcified tuberculous caseating granuloma (tuberculoma); if associated with calcified ipsilateral hilar lymph node, then Ghon complex (or Ranke complex if healed)
  - Recrudescent TB: cavitary lesions and upper lobe disease with hilar adenopathy
  - HIV: atypical findings with primary infection, right upper lobe atelectasis
- CT chest: good sensitivity, tree-in-bud (centrilobular nodules with branching linear opacities)

**Follow-Up Tests & Special Considerations**
- Baseline CBC, creatinine, aspartate aminotransferase, alanine aminotransferase, bilirubin, alkaline phosphatase, visual acuity, and red-green color discrimination (regimens involving ethambutol [EMB])
- Diabetes screen if risk factors present
- HIV: If positive, get baseline CD4 count, viral load, and genotype.
- Check hepatitis B and C if injection drug users, Africa or Asia born, HIV infected or otherwise high risk.
- Extrapulmonary: urine, CSF, bone marrow, and liver biopsy for culture as indicated. Interferon-Gamma (IFN-γ) and adenosine deaminase levels.
- Nonspecific findings: anemia, thrombocytosis, SIADH, hypergammaglobulinemia, monocytosis, sterile pyuria

**Diagnostic Procedures/Other**
- Culture: takes several weeks for definitive results
- Xpert MTB/RIF (rapid molecular test): currently the only FDA-approved molecular assay for pulmonary TB diagnosis and detection of rifampicin resistance in areas with high prevalence of MDR TB

---

**TREATMENT**

**GENERAL MEASURES**
- If clinical suspicion, treat immediately. Prescribing physician is responsible for treatment completion.
- Respiratory and droplet precautions
- Not infectious if favorable clinical response after 2 to 3 weeks of therapy and each of three repeat AFB smears are negative

**MEDICATION**
Use ideal body weight for dosing; DOT recommended for all and required for children, institutionalized patients, nonadherent patients, and nondaily regimens

**First Line**
- LTBI
– Isoniazid (INH) for 9 months at 5 mg/kg/day (max of 300 mg) or 15 mg/kg (max of 900 mg) 2 times per week or
– Isoniazid 15 mg/kg + rifapentine (3HP) 300 to 900 mg weekly for 12 weeks by DOT for age ≥2 years. Recent update by CDC (July 2018); also safe with HIV patients depending on antiretroviral therapy (ART) regimen

**Active TB infection**

– Regimen 1 (preferred)
  – Initial phase:
    – Isoniazid 5 mg/kg, rifampin (RIF) 10 mg/kg (max 600 mg), pyrazinamide (PZA) 15 to 30 mg/kg, and ethambutol (EMB) 15 to 20 mg/kg daily for 8 weeks or
    – INH/RIF/PZA/EMB 5 days/week for 8 weeks
  – Continuation phase:
    – INH/RIF daily for 18 weeks; or, if DOT, INH/RIF 5 days/week for 18 weeks
– Regimen 2 (preferred when more frequent DOT in continuation phase is difficult to achieve)
  – Initial phase:
    – INH/RIF/PZA/EMB daily for 8 weeks or
    – INH/RIF/PZA/EMB 5 days/week for 8 weeks
  – Continuation phase:
    – INH/RIF 3 times per week for 18 weeks
– Regimen 3 (caution if HIV infected or with cavitary disease; missed doses can lead to treatment failure, relapse, and acquired drug resistance)
  – Initial phase: INH/RIF/PZA/EMB 3 times per week for 8 weeks
  – Continuation phase: INH/RIF 3 times per week for 18 weeks
– Regimen 4 (do not use if HIV positive, smear positive, or cavitary disease)
  – Initial phase: INH/RIF/PZA/EMB daily for 14 doses and then twice a week for 12 doses
  – Continuation phase: INH/RIF twice a week for 18 weeks

**Pregnancy Considerations**

- Delay treatment in pregnant patients with LTBI until delivery unless other risk factors (e.g., HIV, immunosuppressed) present.
- Treat TB in pregnancy with INH, RIF, and EMB; add pyridoxine 25–50 mg/day.
- Streptomycin: ototoxic and nephrotoxic; do not use in pregnancy.
- PZA is not used in pregnant women in the United States.
- Congenital infection: from maternal miliary or endometrial TB. PPD, CXR, lumbar puncture, and culture placenta. Treat promptly if suspected.
- Breastfeeding: OK while taking TB drugs; supplement with pyridoxine 25–50 mg/day.

**Pediatric Considerations**

- Children may attend school as long as they are taking the appropriate medications.
- EMB can be used in infants and children.

**ALERT**

- Maximum drug doses: rifampin 600 mg all regimens; pyrazinamide 2,000 mg/day or 4,000 mg 2 times per week; ethambutol 600 mg/day or 4,000 mg 2 times per week
- If patient does not receive PZA for all of the first 2 months, extend treatment to 9 months.
- M. bovis is resistant to PZA; must be treated 9 months
Continue EMB until organism susceptibility to INH plus RIF is determined.
Initiation of ART therapy in HIV-positive patients infected with TB carries an increased risk of immune reconstitution inflammatory syndrome (IRIS). ART should be initiated within first 2 weeks in patients with CD4 <50 and no later than 8–12 weeks with patients with CD4 count >50 in patients with pulmonary TB.

**Second Line**
Fluoroquinolones and injectable aminoglycosides. Use when MDR is suspected or patient intolerance. Pretomanid newly FDA approved for use in XDR-TB

**ISSUES FOR REFERRAL**

**ALERT**
Notify public health authorities for all cases of active TB. Consult infectious disease specialist for drug-resistant TB and HIV-positive patients on ART.

**ADDITIONAL THERAPIES**
- Pyridoxine: 50 mg should be given to all persons at risk for INH neuropathy: pregnant women, diabetes, breastfed infants, HIV positive, alcoholism, chronic renal failure, malnutrition, or advanced age. Give 100 mg daily to patients with pre-existing neuropathy.
- Steroids: recommended for TB meningitis; not recommended for TB pericarditis

**SURGERY/OTHER PROCEDURES**
For extrapulmonary complications (spinal cord compression, bowel obstruction, constrictive pericarditis)

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Negative pressure isolation with personal respirators and droplet precautions
- Three consecutive negative sputum AFB smears are necessary for release from isolation.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Monthly sputum for AFB smear and culture until two consecutive cultures are negative; must confirm this prior to starting continuation phase
- Monthly visits to monitor medication adherence and adverse effects; CXR after 2 months of treatment
- For HIV positive: CD4 count, viral load, CBC, and liver enzymes every 3 months
- Liver enzymes monthly for chronic liver disease, alcohol use, pregnant or postpartum patients. Drug-induced liver injury is most common side effect of treatment. Temporarily halt medications for enzyme increase ≥5 × ULN if asymptomatic or ≥3 × ULN if symptomatic.
- Visual acuity and red-green color monthly if on EMB >2 months or doses >20 mg/kg/day
- If culture positive after 2 months of therapy, reassess drug sensitivity, initiate DOT, coordinate care with public health authorities, and consider infectious disease consultation (if not already involved). Persistent culture-positive patients may warrant extended treatment.
PATIENT EDUCATION
- Emphasize medication adherence.
- Screen and treat close contacts.
- Alert patient that health authorities must be notified.

PROGNOSIS
Few complications and full resolution of infection if medications are taken for full course as prescribed

COMPLICATIONS
- Cavitary lesions can become secondarily infected.
- Risk for drug resistance increases with HIV positive, treatment nonadherence, or residence in area with high incidence of resistance.
- MDR-TB: resistance to INH and rifampicin
- XDR-TB: MDR-TB that is also resistant to fluoroquinolones and at least one second-line injectable drug (9% of MDR)

REFERENCE

SEE ALSO
- Tuberculosis, CNS; Tuberculosis, Latent (LTBI); Tuberculosis, Miliary
- Algorithm: Weight Loss, Unintentional

CODES
ICD10
- A15.9 Respiratory tuberculosis, unspecified
- A15.0 Tuberculosis of lung
- A19.9 Miliary tuberculosis, unspecified

CLINICAL PEARLS
- TB is fully curable when treated appropriately.
- Children and elderly patients exhibit fewer classic clinical features of TB.
- TST and IGRA cannot discern active TB from LTBI.
**TUBERCULOSIS, LATENT (LTBI)**
Trisha K. Patel, DO ● Jacqueline R. Ivey-Brown, MD, FACP

**BASICS**

**DESCRIPTION**
- Latent tuberculosis infection (LTBI) is an asymptomatic, noninfectious condition following exposure to an active case of tuberculosis. LTBI is usually detected by a positive skin test (i.e., purified protein derivative [PPD]) or a positive interferon-γ release assay (IGRA) test.
- Active TB occurs in 5–10% of infected individuals who have not received preventive therapy. Chance of active TB increases with immunosuppression and is highest for all individuals within 2 years of infection; 85% of the cases are pulmonary, which is capable of person-to-person spread via aerosol route.
- Greater than 80% of TB cases in United States result from untreated LTBI (1).
- LTBI treatment is a key component of the TB elimination strategy for the United States.

**ALERT**
The current pace of decline in TB incidence will not eliminate TB in the United States in the 21st century. Extra effort is needed to identify patients with LTBI (2).

**EPIDEMIOLOGY**
- In the United States, high-risk groups include immigrants from Asia, Latin America, Africa, and the Pacific basin; blacks; homeless persons; persons with a history of drug use or history of incarceration; HIV-infected individuals; and health care workers and other immunocompromised individuals (2).
- TB is a major cause of death in individuals infected with HIV (2).
- Newly exposed (particularly children) are also at high risk.
- In 2018, there were 9,029 new tuberculosis (TB) cases reported in the United States, a 0.7% decrease from 2017 (1).
- Among the 9,029 TB cases reported in the United States in 2018, approximately two thirds (6,276 [69.5%]) occurred in non–U.S.-born persons, whereas 2,662 (29.5%) occurred in U.S.-born persons; 91 (1.0%) cases occurred in persons for whom no national origin was documented (1).
- Among non–U.S.-born persons with TB, incidence in 2018 was highest among Asians, followed by Native Hawaiians/Pacific Islanders, non-Hispanic blacks, Hispanics, and American Indian/Alaska Natives, and was lowest among non-Hispanic whites (1,2).
- The highest TB incidence for U.S.-born persons occurred among Native Hawaiians/Pacific Islanders, followed by American Indians/Alaska Natives, blacks, Asians, and Hispanics, and was lowest in whites (1).

**Incidence**
In 2018, a total of 9,029 new tuberculosis (TB) cases were reported in the United States (1).

**Prevalence**
- 13 million people in the United States are infected with TB (1)
- ~1/4 of the world’s population harbors latent TB.
ETIOLOGY AND PATHOPHYSIOLOGY
Mycobacterium tuberculosis, Mycobacterium bovis, and Mycobacterium africanum

RISK FACTORS
- HIV infection, immunosuppression
- Immigrants (from Asia, Latin America, Pacific Islands, Africa, or areas with high rates of TB), including migrant workers
- Close contact with infected individual
- Institutionalization (e.g., prison, nursing home)
- Use of illicit drugs
- Lower socioeconomic or homeless status
- Health care workers
- Chronic medical disease such as diabetes mellitus (DM), end-stage renal disease, cancer, or silicosis; organ transplant (immunosuppression)
- Persons with fibrotic changes on chest x-ray (CXR) consistent with previous TB infection
- Recent TB skin test (tuberculin skin test [TST]) converters
- Laboratory personnel working with mycobacteria
- Organ donors should be screened. If donor is deceased, IGRA testing is still possible.

GENERAL PREVENTION
Screen for LTBI and treat individuals with positive tests.

COMMONLY ASSOCIATED CONDITIONS
- HIV infection (see “Initial Tests (lab, imaging)”)
TST: PPD: 5 U (0.1 mL) intermediate-strength intradermal volar forearm. Measure induration at 48 to 72 hours:

- Positive if induration is (2)
  - >5 mm and patient has HIV infection (or suspected), is immunosuppressed, had recent close TB contact, or has clinical evidence of active or old disease on CXR
  - >10 mm and patient age <4 years or has other risk factors noted earlier
  - >15 mm and patient age >4 years and has no risk factors
- Negative if induration <5 mm on initial test and, if indicated, on second test
- Use the two-step test (administer a second intradermal test 1 to 3 weeks after initial test; measure and interpret as usual) if patient has had no recent PPD and is age >55 years or is a nursing home resident, prison inmate, or health care worker.
- Preferred for children <5 years

The IGRA QuantiFERON-TB® and QuantiFERON-TB GOLD®; T-SPOT® measures the release of interferon by sensitized lymphocytes when exposed to antigens of M. tuberculosis. It is unaffected by prior BCG vaccination, requires only one visit, and has improved sensitivity and specificity but is costly.

Special considerations
- Steroids: false-negative skin test
- Measles vaccine: may suppress tuberculin activity; simultaneous PPD and measles vaccine recommended; if not simultaneous, defer PPD for 4 to 6 weeks after measles vaccine.
- The multiple-puncture tine test is not recommended.
- The history of BCG vaccination should not alter the management of a positive PPD test.
- Disorders that may give a false-negative skin test:
  - Recent viral infection
  - New (<10 weeks) infection
  - Severe malnutrition; HIV; anergy
  - Age <6 months
  - Overwhelming TB

TREATMENT

GENERAL MEASURES
- Must exclude active TB
- Treatment for LTBI is critical for the control and elimination of TB disease. LTBI treatment decreases the risk of active TB and decreases risk of potential spread to others. Treat all persons with LTBI.
- High-risk patients: Treat LTBI at any age if patient has HIV, has had close TB contact, is a recent converter (<2 years), is an IV drug user, has an abnormal CXR, or has a high-risk medical condition.
- Directly observed therapy (DOT) is recommended if patient adherence is not assured. Video DOT is an effective alternative.
  - Use isoniazid (INH) 900 mg and rifapentine 900 mg weekly for 12 weeks.
  - Use INH for 9 months.
  - Acceptable alternative: INH for 6 months
- Treat LTBI during pregnancy if patient has recent infection or is HIV positive (use INH with
pyridoxine, and monitor liver enzymes); otherwise, postpone treatment until after delivery.
• Consult public health or infectious disease specialist for suspected INH resistance in HIV patients.
• Note: Rifampin and pyrazinamide are less often recommended for LTBI treatment due to side effects.
• Exclusions: cirrhosis, active hepatitis, history of excessive alcohol consumption

MEDICATION
• INH and rifapentine (RPT) (3)
  – Patients >2 years: Rifapentine, a rifampin-like drug, can be used to treat LTBI. 900 mg weekly (if patient >50 kg) and INH 15 to 25 mg/kg weekly (rounded to nearest 50 or 100 mg; 900 mg max) for 12 weeks given as DOT. This new, shorter treatment increased rates of completion compared with 9 months of INH (82% vs. 69%), slightly more adverse effects (5% vs. 4%), more costly (3).
    o HIV/AIDS patients are included for this new regimen (4). Children >2 years also have been recently added to this regimen because DOT is not required in children; parent-administered treatment is accepted (4).
• INH alone
  – INH-scored tablets: 100 mg, 300 mg, or syrup 10 mg/mL
    o Daily: adult 300 mg; pediatric 10 to 15 mg/kg (maximum 300 mg)
    o Twice weekly: adult 900 mg; pediatric 20 to 30 mg/kg (maximum 900 mg)
    o Treatment for 9 months; typical completion rates of ≤60%
    o Precautions
      ■ Follow liver function if the patient has history of alcoholism, HBV, HCV, fatty liver, or other signs of liver dysfunction or injury.
      ■ INH: Peripheral neuritis and hypersensitivity are possible. Consider concurrent pyridoxine.
• Alternative: rifampin alone
  – Adults 600 mg/day for 4 months; children 15 mg to 20 mg/kg/day for 6 months (max 600 mg/day).
  – Note: Rifapentine can reduce the effectiveness of hormonal contraception; women on birth control pills should switch to or add a barrier method for the 3 months of latent TB treatment (4).
  – Rifapentine can interact with warfarin—patients require increased monitoring (4).

ADDITIONAL THERAPIES
Pediatric Considerations
• Follow public health recommendations for assessing and treating newborns.
• If mother or household contact has LTBI, skin test all household contacts, and treat all positive PPD.
• If contact has abnormal CXR, separate infant until infectious status is known; if not contagious, monitor infant PPD.
• If mother has disease and is possibly contagious, evaluate infant for congenital TB and test for HIV; separate newborn until mother is noninfectious.
• Treat suspected congenital TB.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Geriatric Considerations

- Before entering a chronic care setting, patients should have two-step PPD using facility protocols.
- INH side effects are more pronounced.
- Discharge criteria
  - Activity, as tolerated
  - No isolation required

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- During preventive therapy for LTBI: monthly visits to assess adherence and monitor for hepatitis and neuropathy; if stable, can monitor less frequently
- If patient asymptomatic, no need to repeat CXR
- Check liver enzymes if patient is symptomatic, HIV positive, has chronic liver disease, uses alcohol, or is pregnant or postpartum. Modify drugs as needed.

DIET

Regular. Consider pyridoxine, 10 to 50 mg/day.

PROGNOSIS

- Generally, there are few complications, and treatment is effective if medications are taken as prescribed.
- Retreatment is not necessary.

COMPLICATIONS

Recrudescent TB

REFERENCES

ADDITIONAL READING

SEE ALSO
Tuberculosis; Tuberculosis, Miliary

CODES
ICD10
R76.11 Nonspecific reaction to skin test w/o active tuberculosis

CLINICAL PEARLS
- Treatment of LTBI is crucial to the control and elimination of TB disease in the United States.
- Screen foreign-born persons for latent TB, and treat those who are positive.
- Screen household contacts of patients who are PPD positive.
- The interferon-γ (IGRA) blood test is unaffected by prior BCG vaccination.
TYPHOID FEVER
Douglas W. MacPherson, MD, MSc–CTM, FRCPC

BASICS
- A common enteric bacterial disease transmitted by ingestion of contaminated food or water
- Most cases in the United States are imported from endemic areas of South or Southeast Asia and Latin America.
- Drug-resistant salmonellae acquired in Latin America or Asia are common as are high levels of resistance.

DESCRIPTION
- Typhoid fever is an acute systemic illness in humans caused by Salmonella typhi.
  - Classic example of enteric fever caused by Salmonella bacterium
- Enteric fevers due to Salmonella paratyphi can present in a manner similar to classic typhoid fever.
- Typhoid is endemic in developing nations with poor sanitation. Most cases in North America and other developed nations are acquired after travel to disease-endemic areas.
- Travelers may be at greater risk of typhoid.
- Mode of transmission is fecal–oral through ingestion of contaminated food (poultry or milk) or water.
- Incubation period varies from 7 to 21 days.
- System(s) affected: gastrointestinal; pulmonary; skin/exocrine
- Synonym(s): typhoid; typhus abdominalis; enteric fever; nervous fever; slow fever

Geriatric Considerations
Disease is more serious in the elderly.

Pediatric Considerations
Disease is more serious in infants and milder in children.

EPIDEMIOLOGY
Although typhoid outbreaks have been described in the United States, most cases are reported in international travelers returning from endemic transmission areas.
- Predominant age: all ages
- Predominant sex: male = female

Incidence
In the United States, 300 to 500 new cases per year. Worldwide, typhoid fever infects over 21 million people/year with ~200,000 deaths.

ETIOLOGY AND PATHOPHYSIOLOGY
- Historically, typhoid fever (untreated) occurs in several week-long stages.
- The initial infection is transmitted via the fecal–oral route, with resultant bacteremia and sepsis. Involvement of the bowel wall (Peyer patch) rarely may be associated with bleeding from the bowel or bowel perforation.
- The first stage involves fluctuations in temperature with relative bradycardia (Faget sign).
Other symptoms include headache, cough, malaise, epistaxis, and abdominal pain.

- The second stage involves higher fever (with persistent relative bradycardia). Mental status changes are possible (agitation—“nervous fever”). Rose spots appear on the chest and abdomen. In some patients, abdominal pain is common as is constipation or diarrhea (with characteristic malodorous “pea soup” appearance).
- The third week is when most complications occur due to intestinal hemorrhage or encephalitis.
- The final week is defervescence and recovery.
- A chronic carrier state may occur with S. typhi shedding in the stools. Potential person-to-person transmission may occur. In a chronic carrier state, S. typhi resides in the biliary tract and gallbladder. Chronic suppressive antimicrobials may clear the carrier state; in rare cases, cholecystectomy performed to clear S. typhi carrier state

**RISK FACTORS**

- Consider in patients presenting with fever after tropical travel or exposure to a chronic carrier.
- Small inocula of Salmonella typhi (~100,000 organisms) cause disease in >50% of healthy individuals.

**GENERAL PREVENTION**

- Food and water precautions help prevent all enteric infections, including typhoid fever.
- Avoid tap water, salad/raw vegetables, unpeeled fruits, and dairy products in tropical travel.
- Avoid undercooked poultry or poultry products left unrefrigerated for prolonged periods.
- Wash hands before and after food preparation.
- For high-risk travel to an endemic area, consider typhoid vaccination (1)[A],(2)[A].
  - Parenteral ViCPS or capsular polysaccharide typhoid vaccine (Typhim Vi) or
  - Ty21a or live oral typhoid vaccine (Vivotif Berna), particularly if prolonged risk (>4 weeks)
- Consider vaccination for workers exposed to S. typhi or those with close contact with a carrier of S. typhi.
- Occupational health and safety precautions. Consider screening of domestic and commercial food handlers.

**DIAGNOSIS**

Assess clinical presentation and exposure history, including travel and exposures to S. typhi carriers.

**HISTORY**

- Travel history to an endemic region and exposure to contaminated food or water
- Exposure to a chronic S. typhi carrier
- Fever, headache
- Malaise
- Abdominal discomfort/bloating/constipation
- Diarrhea (less common)
- Dry cough
- Confusion/lethargy

**PHYSICAL EXAM**

- Fever with relative bradycardia
Cervical adenopathy
Conjunctivitis
Rose spot (transient erythematous maculopapular rash in anterior thorax or upper abdomen)
Splenomegaly
Hepatomegaly

DIFFERENTIAL DIAGNOSIS
- Enteric fever caused by nontyphoid Salmonella spp.
- “Enteric fever–like” syndrome caused by Yersinia enterocolitica, pseudotuberculosis, and Campylobacter spp.
- Infectious hepatitis
- Malaria, dengue
- Atypical pneumonia
- Infectious mononucleosis
- Subacute bacterial endocarditis
- Tuberculosis
- Brucellosis; Q fever; typhus
- Rickettsial diseases
- Toxoplasmosis
- Viral infections: Epstein-Barr virus (EBV), cytomegalovirus (CMV), viral hemorrhagic agents

DIAGNOSTIC TESTS & INTERPRETATION
Enteric fevers/typhoid syndromes are rare in the United States. Therefore, a high level of clinical suspicion is required.
- Definitive diagnosis is by culture of S. typhi from blood or other sterile body fluid.
- Isolation of S. typhi in sputum, urine, or stool leads to a presumptive diagnosis.
- Serology is nonspecific and typically not useful.
- If there are multiple negative blood cultures or patient has recently been on antibiotic therapy, diagnostic yield is better with bone marrow culture.
- Anemia, leukopenia (neutropenia), thrombocytopenia, or evidence of disseminated intravascular coagulopathy. Elevated liver enzymes are common.
- Suspect intestinal perforation (consider serial plain abdominal films looking for evidence of perforation) in ill patients complaining of persistent abdominal tenderness.

Diagnostic Procedures/Other
- Bone marrow aspirate for culture of S. typhi is more sensitive than blood cultures but rarely used as a primary investigation.
- Bone marrow aspiration may be done for evaluation of a fever of unknown origin.

Test Interpretation
Classically, bowel pathology shows mononuclear lymphoid proliferation, especially Peyer patches of the terminal ileum.

TREATMENT
- Treatment of typhoid disease and chronic carrier states must be determined on an individual basis. Factors to consider include age, public health and occupational health risk (e.g., food
(handler, chronic care facilities, medical personnel), intolerance to antibiotics, and evidence of biliary tract disease.

- Awareness of emerging drug-resistant *S. typhi* strains and the epidemiology of the patient’s exposure help direct primary therapy. Knowledge of local resistance patterns for presumptive treatment or laboratory sensitivity also guides therapy. Fluoroquinolone-resistant *S. typhi* is common in Asia.

**GENERAL MEASURES**
- Fluid and electrolyte support
- Strict isolation of patient’s linen, stool, and urine
- Consider serial plain abdominal films for evidence of perforation, usually in the 3rd to 4th week of illness.
- For hemorrhage: blood transfusion and management of shock

**MEDICATION**

**First Line**
- Chloramphenicol: pediatric 50 mg/kg/day PO QID for 2 weeks; adult dose 2 to 3 g per day PO divided q6h for 2 weeks or
- Amoxicillin: pediatric 100 mg/kg/day (max 2 g) QID PO for 2 weeks; adults 500 mg q6h for 2 weeks or
- Ciprofloxacin: 500 mg PO BID for 2 weeks, indicated in multiple-drug-resistant typhoid
  - Has been used safely in children; WHO recommends as first line in areas with drug resistance to older first-line antibiotics.
  - Fluoroquinolones may prevent clinical relapse better than chloramphenicol (3)[A].
- Ceftriaxone: pediatric 100 mg/kg/day for 2 weeks; adult dose: 1 to 2 g IV once daily for 2 weeks or
- Azithromycin: pediatric 10 to 20 mg/kg (max 1 g) PO daily for 5 to 7 days; adult dose: 1 g PO once followed by 500 mg PO daily for 5 to 7 days
- Chronic carrier state
  - Amoxicillin: 4 to 5 g/day plus probenecid 2 g/day QID for 6 weeks (for patients with normal gallbladder function and no evidence of cholelithiasis)
  - Ciprofloxacin: 500 mg PO BID for 4 to 6 weeks is also efficacious. Chloramphenicol resistance has been reported in Mexico, South America, Central America, Southeast Asia, India, Pakistan, Middle East, and Africa.
- Contraindications: Refer to manufacturer’s profile.
- Precautions: Rarely, Jarisch-Herxheimer reaction appears after antimicrobial therapy.
- Significant possible interactions: Refer to manufacturer’s profile for each drug.

**Second Line**
- Trimethoprim–sulfamethoxazole: 1 double-strength tablet twice/day for 10 days (Note: Drug resistance is common; local resistance patterns and expert consultation should guide treatment.)
- Furazolidone: 7.5 mg/kg/day PO for 10 days; in uncomplicated multidrug-resistant typhoid; safe in children; efficacy >85% cure

**Pregnancy Considerations**
Ciprofloxacin therapy is relatively contraindicated in children and in pregnant patients.
ISSUES FOR REFERRAL
Complications of sepsis, bowel perforation

SURGERY/OTHER PROCEDURES
- Complications: bowel perforation
- Cholecystectomy may be warranted in carriers with cholelithiasis, relapse after therapy, or intolerance to antimicrobial therapy.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Inpatient if acutely ill
- Outpatient for less ill patient or for carrier
- Observe enteric precautions.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Bed rest initially and then activity as tolerated

Patient Monitoring
See “General Measures.”

DIET
NPO if abdominal symptoms are severe. With improvement, begin normal low-residue diet, with high-calorie supplementation if malnourished.

PATIENT EDUCATION
- Discuss chronic carrier state and its complications.
- For family members, travelers, or workers at risk, educate about food/water hygiene and provide vaccination.
- Educate patients that the typhoid vaccines do not protect against S. paratyphi infection.
- Typhoid vaccines protect 50–80% of recipients (not 100%). Efficacy wanes over 2 to 4 years.
- CDC patient handout: http://www.cdc.gov/vaccines/hcp/vis/vis-statements/typhoid.html

PROGNOSIS
Overall prognosis is good; with appropriate treatment, <2% mortality rate, 15% relapse rate with some antibiotic treatments, and 3% bowel perforation

COMPLICATIONS
- Intestinal hemorrhage and perforation in distal ileum
- Patients (up to 3%) may become chronic carriers-persistent stool excretor of S. typhi for >1 year.
- Seeding of the biliary tract may become a focus for relapse of typhoid fever: most common in females and older patients (>50 years of age)
- Osteomyelitis is more common in patients with sickle cell anemia, systemic lupus erythematosus, and hematologic neoplasms, as well as in immunosuppressed hosts.
- Endovascular infection in the elderly and in patients with a history of bypass operation or aneurysm
- Rarely, endocarditis or meningitis
REFERENCES

ADDITIONAL READING

CODES

ICD10
- A01.00 Typhoid fever, unspecified
- Z22.0 Carrier of typhoid
- A01.03 Typhoid pneumonia

CLINICAL PEARLS

- Consider typhoid (along with malaria, dengue, and other travel-associated infections) in febrile travelers returning from endemic areas (Latin America, sub-Saharan Africa, South Asia).
- Routine blood cultures detect S. typhi but may be negative if antibiotics are administered prior to testing.
- A history or documentation of vaccination against S. typhi does not exclude the diagnosis of typhoid fever.
BASICS

An infectious disease syndrome caused by several rickettsial bacterial organisms resulting in acute, chronic, and recurrent disease (1)[C]

DESCRIPTION

- Acute infection caused by three species of Rickettsia
  - Epidemic typhus: human-to-human transmission by body louse; primarily in setting of refugee camps, war, famine, and disaster. Recurrent disease occurs years after initial infection and can be a source of human outbreak. Flying squirrels are a reservoir.
  - Endemic (murine) typhus: spread to humans by rat flea bite
  - Scrub typhus: infection and infestation of chiggers and of rodents to humans by the chigger; primarily in Asia and western Pacific areas
- System(s) affected: endocrine/metabolic; hematologic/lymphatic/immunologic; pulmonary; skin/exocrine
- Synonym(s): louse-borne typhus; Brill-Zinsser disease; murine typhus

EPIDEMIOLOGY

- Epidemic and endemic typhus: rare in the United States (outside of South Texas)
- Scrub typhus: travelers returning from endemic areas

Incidence

Endemic typhus: <100 cases annually, primarily in states around the Gulf of Mexico, especially South Texas; underreporting suspected

ETIOLOGY AND PATHOPHYSIOLOGY

- Epidemic typhus by Rickettsia prowazekii
- Endemic typhus by Rickettsia typhi (2)[A]
- Scrub typhus by Rickettsia tsutsugamushi

RISK FACTORS

- Vector exposure
- Travel to endemic countries

Geriatric Considerations

Elderly may have more severe disease.

GENERAL PREVENTION

Vector control:

- Scrub typhus: protective clothing and insect repellents
- Endemic typhus: ectoparasite and rodent control
- Epidemic typhus: delousing and cleaning of clothing; vaccine for those at high risk of exposure (typhus vaccine production discontinued in the United States)
**DIAGNOSIS**

Typhus syndromes are rare in the United States. A high level of clinical suspicion is necessary.

**HISTORY**

Travel or other risk exposure
- Fever, chills
- Intractable headache
- Myalgias, malaise
- Cough, rash, ocular pain

**PHYSICAL EXAM**

- General
  - Fever
  - Relative bradycardia (scrub typhus)
- Epidemic typhus
  - Incubation period ~1 week
  - Macular or maculopapular rash beginning on trunk ~5th day of illness
  - Nonproductive cough
  - Pulmonary infiltrates
- Endemic typhus
  - Incubation period 1 to 2 weeks
  - Macular or maculopapular rash beginning on trunk 3rd to 5th day of illness
- Scrub typhus
  - Incubation period 1 to 3 weeks
  - Eschar at bite site
  - Regional lymphadenopathy
  - Generalized lymphadenopathy
  - Splenomegaly
  - Macular or maculopapular rash beginning on trunk approximately 5th day of illness
  - Relative bradycardia early in disease
  - Ocular pain
  - Conjunctival injection

**DIFFERENTIAL DIAGNOSIS**

- Other rickettsial disease: Rocky Mountain spotted fever; ehrlichiosis; Mediterranean spotted fever (boutonneuse fever) (*Rickettsia conorii*)
- Bacterial meningitis; meningococcemia
- Measles, rubella
- Toxoplasmosis
- Leptospirosis
- Typhoid fever
- Dengue, malaria
- Relapsing fever
- Secondary syphilis
- Viral syndromes: mononucleosis, acute retroviral syndrome
**DIAGNOSTIC TESTS & INTERPRETATION**
- Specific serologies with rising antibody titer
- If suspected, isolate Rickettsia in qualified laboratory to minimize the risk of laboratory-acquired infection.
- CDC Rickettsial Zoonoses Branch 404-639-1075

**Initial Tests (lab, imaging)**
- CBC often normal
- Weil-Felix serologic reaction may be positive; test hampered by low sensitivity and nonspecificity; epidemic and endemic typhus, 4-fold titer rise or titer >1/320 to OX19; scrub typhus, 4-fold rise in titer to OXK
- Hyponatremia in severe cases
- Hypoalbuminemia in severe cases
- Recent antibiotic exposure may alter lab results.

**Test Interpretation**
Diffuse vasculitis on skin biopsy

---

**TREATMENT**
Initiate treatment based on epidemiologic risk and clinical presentation.

**GENERAL MEASURES**
- Skin and mouth care
- Supportive care—directed at complications

**MEDICATION**

**First Line**
- Begin treatment when diagnosis is likely and continue until clinically improved and the patient is afebrile for at least 48 hours; usual course is 5 to 7 days.
- Children ≥8 years of age and adults
  - Doxycycline IV/PO: adults 100 mg q12h, children ≤45 kg: 5 mg/kg/day divided twice daily (max of 200 mg/day); >45 kg: adult dosing
  - Children ≤8 years of age: risk of dental staining from tetracyclines minimal with short courses
  - Tetracycline: 25 mg/kg PO initially and then 25 mg/kg/day in equally divided doses q6h
- Children ≤8 years of age, pregnant women, or if typhoid fever is suspected
  - Chloramphenicol: 50 mg/kg PO initially and then 50 mg/kg/day in equally divided doses q6h
  - If severely ill, chloramphenicol sodium succinate: 20 mg/kg IV initially, infused over 30 to 45 minutes and then 50 mg/kg/day infused in equally divided doses q6h until orally tolerable
  - Azithromycin, fluoroquinolones, and rifampin alternatives depending on scenario
- Precautions and interactions: Refer to the manufacturer’s profile for each specific drug.

**Second Line**
- Doxycycline: single oral dose of 100 or 200 mg PO for those in refugee camps, victims of
disasters, or in the presence of limited medical services
- Isolated reports indicate that erythromycin and ciprofloxacin are effective.
- Azithromycin 1,000 mg PO once a day for 3-day course is effective for scrub typhus; better tolerated than doxycycline but more expensive
- Rifampin may be effective in areas where scrub typhus responds poorly to standard antirickettsial drugs.

**ISSUES FOR REFERRAL**
Infectious disease consultation is recommended. Contact CDC and local public health authorities.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Outpatient care unless severely ill
- Severely ill or constitutionally unstable (e.g., shock)

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
**Patient Monitoring**
- Admit severely ill patients.
- If treated as an outpatient, ensure regular follow-up to assess clinical improvement and resolution.

**DIET**
As tolerated

**PATIENT EDUCATION**
Travel advice (minimize exposure risks, vector avoidance, vaccination as appropriate)

**PROGNOSIS**
- Recovery is expected with prompt treatment.
- Relapses may follow treatment, especially if initiated within 48 hours of onset (this is not an indication to delay treatment). Treat relapses the same as primary disease.
- Without treatment, the mortality rate of typhus is 40–60% for epidemic, 1–2% for endemic, and up to 30% for scrub disease.
- Mortality is higher among the elderly.

**COMPLICATIONS**
Organ-specific complications (particularly in the 2nd week of illness): azotemia, meningoencephalitis, seizures, delirium, coma, myocardial failure, hyponatremia, hypoalbuminemia, hypovolemia, shock, and death

**REFERENCES**

ADDITIONAL READING

CODES

ICD10
- A75.9 Typhus fever, unspecified
- A75.0 Epidemic louse-borne typhus fever d/t Rickettsia prowazekii
- A75.2 Typhus fever due to Rickettsia typhi

CLINICAL PEARLS

- Consider typhus (along with malaria and dengue) in febrile travelers returning from endemic areas.
- Rickettsial infections typically present within 2 to 14 days. Febrile illnesses presenting >18 days after travel are unlikely to be rickettsial.
- Routine blood cultures do not detect Rickettsia.
- Prior vaccination does not exclude typhus.
ULCER, APHTHOUS
Cynthia Y. Ohata, MD • Trent J. Auguston, MD

**BASICS**

**DESCRIPTION**
- Self-limited, painful ulcerations of the nonkeratinized oral mucosa, which are often recurrent
- Synonyms: canker sores; aphthae; aphthous stomatitis
  - Comes from aphth meaning “to set on fire” or “to inflame” in Greek; first used by Hippocrates (460–370 BC) to categorize oral disease (1)
- Classification based on severity (2)
  - Simple aphthosis
    - Common
    - Episodic
    - Infrequent (<7 episodes annually)
    - Prompt healing, few ulcers
    - Minimal pain, little disability, limited to oral cavity
    - Self-limiting
    - Resolution in 1 to 2 weeks
    - Responds well to local treatments
  - Complex aphthous ulcers
    - Uncommon
    - Episodic or continuous
    - Slow healing
    - Few to many ulcers
    - Frequent or continuous ulceration
    - Short or non-existent disease free intervals
    - Marked pain
    - Major disability
    - Often need systemic treatments
    - May have genital aphthae
- Ulcer morphology (2,3,4)
  - Minor aphthous ulcers
    - Age of onset 5–19 years
    - Usually <10 mm in diameter
    - Self-limited, healing within 4 to 14 days
    - Rarely affects the roof of the mouth
    - Nonscarring
  - Major aphthous ulcers
    - Age of onset 10–19 years
    - Usually >10 mm in diameter
    - Can affect the roof of the mouth and pharynx
    - May take weeks to months to heal
    - Generally more painful than minor aphthous ulcers
    - May cause scarring and be accompanied by fever and malaise
– Herpetiform ulcers (4)
  o Age of onset 20–29 years
  o Usually 1 to 2 mm in diameter, form larger lesions when coalesced
  o No association with herpes simplex virus
  o Occur in small clusters numbering 10s to 100s, lasting 1 to 4 weeks
  o Generally more painful than minor aphthous ulcers
  o Scarring unusual
  o May also affect the palate, gingiva, and pharynx
  o More common in women

**EPIDEMIOLOGY**
- Most common ulcerative disease of the oral mucosa (4), affecting 5–25% of the population (3)
- More common in patients between 10 and 40 years of age, women, Caucasians, nonsmokers, and those of higher socioeconomic status (3,4)
- Less frequent with advancing age
- Less frequent in pregnancy
- Increase in occurrence during luteal phase of menstrual cycle (5)
- Minor aphthous ulcers
  – Most common: 70–85% of all aphthae (3)
- Major aphthous ulcers
  – 10–15% of all aphthae (3)
- Herpetiform
  – Least common: 5–10% of all aphthae (3)

**Incidence**
5% to 50% depending on ethnic and socioeconomic groups (4)

**Prevalence**
Lifetime prevalence of 5–60% (4)

**ETIOLOGY AND PATHOPHYSIOLOGY**
Exact etiology unknown, and likely multifactorial; association with stress-induced rise in salivary cortisol, multiple human leukocyte antigens (HLAs), cell-mediated immunity (4)

**RISK FACTORS**
- Genetic factors: children with both parents having recurrent aphthous stomatitis (RAS) have a 90% chance of developing aphthosis themselves (4) with greater severity
- Associations with specific HLA subtypes (4)
- DNA polymorphisms for NOD-like receptor 3, TLR 4, IL-6
- Local trauma: sharp teeth, dental treatments, or mucosal injury secondary to toothbrushing
- Sodium lauryl sulfate–containing toothpaste
- Increased stress and anxiety
- Nutritional deficiencies: iron, zinc, vitamin B complex, and folate
- Homocysteinemia
- Immunodeficiency
- Recent cessation of tobacco use
- Food sensitivity: to benzoic acid/cinnamaldehyde
- Medications (1)
- NSAIDs
- β-Blockers
- Alendronate
- Methotrexate
- ACE inhibitors
- Neutropenia
- Anemia
- Endocrine alterations (i.e., menstrual cycle) (3)
- Helicobacter pylori infection
- Underlying medical disorders (e.g., celiac, irritable bowel syndrome, Behçet disease)
- S. sanguinis (2)[A]

**DIAGNOSIS**

Diagnosis is made by history and clinical presentation. Lab work is rarely contributory (3)[A].

**HISTORY**

- May experience prodrome of burning sensation of oral mucosa 2 to 48 hours prior to appearance of ulcers
- Patients typically complain of oral ulcerations, which are painful and exacerbated by movement of the mouth. Exacerbation may also be reported with certain foods (hot, spicy, acidic, or carbonated foods or drinks) (3).
- Ask about ulcerative lesions of other anatomic areas, family history, prior history of aphthous ulcers (3) and new medications prior to onset of ulcers (1).

**PHYSICAL EXAM**

- Round or ovoid ulcerations generally <10 mm in size; covered with a grayish-white pseudomembrane surrounded by an erythematous halo
- Ulcers are typically found in the buccal or lip mucosa, ventral tongue, soft palate, or oral vestibule; rarely on the roof of the mouth or lips
- Evaluate for signs of secondary infection: elevated temperature, increased surrounding edema, or pus drainage.

**DIFFERENTIAL DIAGNOSIS**

- Oral trauma
  - Biting
  - Dentures
- Infection (1)
  - Herpes virus (HSV stomatitis): vesicular lesions on keratinized tissue (dorsal tongue, vermillion border); generally not present on mucosa, often with prodromal symptoms (fever, headache, malaise) (1)[C]
  - HIV: Ulcerations have lengthened healing time and tend to be more painful (4).
  - Hand-foot-mouth disease: small vesicles within the oral cavity, along with lesions on the hands and feet
  - Association with H. pylori remains controversial (4).
- Mucocutaneous syndromes; especially if chronic or nonhealing
  - Lichen planus
– Pemphigus

• Medication induced
  – Fixed drug eruptions
  – Linear IgA bullous dermatosis: tense vesicles or bullae appearing 1–15 days after initiation of medication, most commonly caused by vancomycin (1)

• Malignancy: Investigate and closely monitor nonhealing lesions, especially those with leukoplakia or ipsilateral cervical lymphadenopathy.

• Systemic disease should be considered, causing aphthous-like ulcerations.
  – Particularly in adults with their first episode or lesions elsewhere (3)[A]
    – Behçet disease: autoimmune systemic vasculitis usually involving mucous membranes
      o Genital and oral ulceration
      o Uveitis
  – Reiter syndrome: reactive arthritis, preceded by infection, usually of the genital tract (3)[A]
    o Uveitis
    o Urethritis
    o HLA-B27–associated arthritis

• Sweet syndrome: acute neutrophilic dermatitis
  o Fever, sudden onset
  o Erythematous skin plaques/papules, well demarcated
  o Leukocytosis
  o 50% of patients have an associated malignancy.
  o Most often in middle-age females

– Inflammatory bowel disease (IBD): Crohn disease, ulcerative colitis
  o 20% of patients with Crohn disease experience recurrent oral ulcers (1).
  o Bloody or persistent diarrhea
  o Weight loss

– PFAPA syndrome (1)
  o Periodic fevers (3–6 days occurring every 4–8 weeks), aphthous ulcers, pharyngitis, adenitis, abdominal pain, and joint pain
  o Tonsillectomy may be curative in refractory cases.

– Cyclic neutropenia (1)
  o Recurrent fevers (every 3 weeks) associated with infections, occasionally occurring intraorally
  o Begins in childhood

– Systemic lupus erythematosus (SLE): autoimmune vascular collagen disease
  o Oral lesions have great variability, including recurrent ulceration.

– Gluten-sensitive enteropathy (celiac disease) (4)
  o Weight loss and signs of malabsorption
  o Bloating and diarrhea

**DIAGNOSTIC TESTS & INTERPRETATION**

May consider complete blood count; zinc; folic acid; ferritin; vitamins B₁, B₂, B₆, and B₁₂ to evaluate for systemic causes in severe or recurrent cases

**Follow-Up Tests & Special Considerations**

• HIV is associated with increased amount of ulcers and increased healing time.

• Biopsy and viral cultures for nonhealing ulcers or atypical presentations
**Rheumatologic serology if underlying systemic disease is suspected**

---

### TREATMENT

#### GENERAL MEASURES
Management is symptomatic. Goal is to reduce inflammation and relieve pain.

#### MEDICATION
In general, the goals of treatment depend on the extent of ulceration and frequency of outbreaks.

**First Line**
- Topical corticosteroids (to improve healing time and symptoms) (1)[C],(3,4)
  - Adverse effects: may increase risk of oral candidiasis (more likely with higher potency formulations)
  - Topical steroid preparations
    - Triamcinolone 0.1% dental paste
      - Apply sparingly to ulcers 3 times daily for up to 2 weeks or until ulcer resolution.
    - Fluocinonide 0.05% gel or ointment
      - Apply sparingly to ulcers 4 times daily for up to 2 weeks or until ulcer resolution.
    - Dexamethasone 5 mg/5 mL elixir
      - Rinse for 3 minutes and spit 4 times daily until ulcer resolution.
- Topical anesthetics (to reduce symptoms only) (1)[C],(3)[C]
  - Preparations
    - Lidocaine 2% gel or spray
      - Apply 4 times daily or prior to eating as needed for pain for up to 2 weeks or until ulcer resolution.
    - Hyaluronic acid 2% gel
      - Apply 2 times per day for 2 weeks until ulcer resolution.
  - Adverse effects: may cause initial stinging
- Antimicrobial mouth rinses (improve healing time, decrease pain, and may prevent recurrence) (3,4)
  - Preparations
    - Chlorhexidine aqueous mouthwash 0.12% or 0.2% (1)[C],(3)[C]
      - Use 3 times daily while lesions persist.
      - May cause superficial tooth staining
    - Doxycycline (1)[C],(3)[C]
      - 100 mg in 10 mL of water
      - Use rinses for 2–3 minutes, 4 times per day for 3 days.
- Topical immunomodulators (improve healing time, reduce symptoms, and prevent recurrence when used in prodromal phase) (3)[A],(4)[C]
  - Adverse effects: may cause stinging sensation
  - Preparation
    - Amlexanox 5% oral paste
      - Apply to ulcers 4 times daily for up to 2 weeks or until ulcer resolution.

**Second Line**
Systemic corticosteroids—rescue therapy in acute, severe, recurrent outbreaks (3)[C],[4]
  – Prednisone 0.75 mg/kg/day, tapered by 0.25 mg/kg/day every 2 weeks
  – Montelukast 10 mg daily can have similar efficacy to steroids (1)[C].
Colchicine, pentoxifylline, thalidomide, and dapsone have been used with variable success but
should be used with caution due to side effects (3)[C],[4].
Antibiotics—penicillin G potassium, 50 mg 4 times daily for 4 days (3)[C]

ISSUES FOR REFERRAL
Otolaryngology or dental referral if lesions have not resolved as expected

ADDITIONAL THERAPIES
Vitamin B\textsubscript{12} supplementation may be effective in a subset of the population in which
nutritional deficiency is the cause (3,4).
Vitamin C 2000 mg/day may also be an effective adjunctive therapy given its
antiinflammatory properties (1,3).
H. pylori eradication has been associated with lower number of aphthous lesions (4).

SURGERY/OTHER PROCEDURES
Chemical cautery with silver nitrate (reduces ulcer pain but not healing time).
Ozone application is an emerging therapy that decreases pain and improves healing time in
small studies.
Use of Nd:YAG laser has been associated with faster healing of ulcers (3)[C].

COMPLEMENTARY & ALTERNATIVE MEDICINE
Zinc can provide therapeutic and prophylactic improvement, and some homeopathic solutions
have improved pain and size of lesions without intolerable side effects (3)[C].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Evaluation for infection, mucocutaneous or systemic disease, or malignancy should be pursued
for nonhealing lesions or lesions with lymphadenopathy or unusual presentation.

Patient Monitoring
Aphthous ulcers are often recurrent, so patients should be monitored for recurrence.

DIET
Deficiencies of iron, vitamin B\textsubscript{12}, and folic acid are significantly associated with recurrent
aphthous ulcers (1,3,4).

PATIENT EDUCATION
  – Avoid potentially irritating food or drink:
    – Spicy, acidic, hot
    – Carbonated beverages
    – Abrasive/hard foods (e.g., chips, nuts)
  – Behavior modification to reduce dental trauma with toothbrush or bruxism

PROGNOSIS
Varies from single or infrequent recurrences of few, mild, self-resolving lesions to chronic, large, or deep painful lesions. Complex cases can cause significant discomfort and dysfunction. Symptoms improve with age.

**COMPLICATIONS**

Aphthous ulcers can provide a site for infection and can leave scars (3).

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

K12.0 Recurrent oral aphthae

**CLINICAL PEARLS**

- Aphthous ulcers are the most common chronic disease of the oral cavity.
- Most cases are mild, self-limited episodes.
- Appropriate treatment should be aimed at symptom control and promotion of healing.
- Nonhealing ulcers, extraoral involvement, and sudden onset in adulthood require additional workup.
ULCERATIVE COLITIS
George Clement, MD  •  Elise Leisinger, DO

BASICS

DESCRIPTION
- Chronic relapsing and remitting inflammatory disease of the bowel causing recurrent episodes of diarrhea that is often bloody and accompanied by abdominal pain, incontinence, fever, and weight loss
- Marked by inflammatory colonic mucosal changes
- Colonic involvement is universal but may be accompanied by large joint arthritis, ocular inflammation, skin lesions, biliary disease, liver disease, thromboembolic disease, and (rarely) pulmonary complications.

EPIDEMIOLOGY

Incidence
- North America: 19.2/100,000 person-years (1)
- Europe: 24.3/100,000 person-years (1)
- Asia/Middle East: 6.3/100,000 person-years (1)

Prevalence
- North America: 249/100,000 persons (1)
- Europe: 505/100,000 persons (1)

Pregnancy Considerations
- Increased risk of preterm delivery and small for gestational age birth
- 30% with inactive disease relapse in pregnancy
- Management with gastroenterologist and/or maternal–fetal medicine specialist/obstetrician is recommended.

ETIOLOGY AND PATHOPHYSIOLOGY
- Idiopathic; hypothesized association with autoimmune dysfunction, genetic predisposition, diet, and colonic microbiome
- Almost universally involves terminal colon, >95% of patients have rectal involvement, 50% have disease limited to rectum and sigmoid; 20% have pancolitis.

Genetics
Moderate heritability. Specific genetic markers have not been identified.

RISK FACTORS
- Age: variable, peak incidence among ages 15 to 40 years
- First-degree relative with ulcerative colitis (UC)
- Theorized risk factors include disruption of colonic microbiome by diet or infection, dietary factors (Western diet in particular), antibiotic use, lack of breastfeeding in infant, obesity, and NSAID use.

GENERAL PREVENTION
No known preventive measures

**Pediatric Considerations**
- Breastfeeding may protect against pediatric inflammatory bowel disease (IBD).
- UC more likely pancolonic at onset and shorter time from diagnosis to colectomy (median 11 years)

**COMMONLY ASSOCIATED CONDITIONS**
- Arthritis: large joint, sacroiliitis, ankylosing spondylitis
- Pyoderma gangrenosum (rare)
- Erythema nodosum (common)
- Aphthous ulcers
- Episcleritis and uveitis (rare)
- Autoimmune liver disease (rare)
- Fatty liver (common)
- Liver cirrhosis (rare)
- Primary sclerosing cholangitis (rare)
- Bile duct carcinoma (rare)
- Thromboembolic disease (rare)
- Colon cancer (rare)
- Anemia (rare)
- Pulmonary diseases (very rare)

**DIAGNOSIS**

**HISTORY**
- Frequent diarrhea, may be bloody or include mucus
- Frequent, small bowel movements, associated with tenesmus, colicky abdominal pain, urgency, and fecal incontinence
- Onset is gradual and progressive over weeks.
- Episodes are sometimes accompanied by fever, weight loss, fatigue, and anemia.
- Predominant age of onset: 15 to 40 years; smaller peak in ages 50 to 80 years

**PHYSICAL EXAM**
- Often normal
- Abdominal tenderness
- Presence of blood on rectal exam
- In severe disease: fever, hypotension, tachycardia, pallor, loss of subcutaneous fat, muscle atrophy, peripheral edema

**DIFFERENTIAL DIAGNOSIS**
- Crohn disease
- Infectious colitis: bacterial, parasitic, or viral (cytomegalovirus [CMV])
- Diverticular colitis
- Diversion colitis in patients with prior bowel surgery
- Medication-induced colitis
- Radiation colitis
Graft versus host disease
Celiac disease

**DIAGNOSTIC TESTS & INTERPRETATION**
- Clinical presentation and studies are used to determine severity (2).
- Mild: <4 stools daily with or without blood, no systemic symptoms, normal erythrocyte sedimentation rate (ESR) (2)
- Moderate: >4 stools daily, no or minimal systemic symptoms (2)
- Severe: >6 blood stools daily, evidence of systemic illness with fever, tachycardia, anemia, or high ESR (2)
- Fulminant: usually >10 stools daily, continuous bleeding, signs of systemic illness as in “severe,” abdominal tenderness, blood transfusion requirement, colonic dilation on abdominal x-rays (2)

**Initial Tests (lab, imaging)**
- Complete blood count: Leukocytosis and anemia support diagnosis.
- BMP: urea and electrolyte abnormalities; hypokalemia supports diagnosis.
- Liver function tests (LFTs): liver function abnormalities; low albumin indicates severe disease.
- ESR or C-reactive protein elevation supports diagnosis and can help define severity.
- Ferritin and transferrin if anemic to determine iron deficiency versus chronic disease
- Vitamin B₁₂ and folate levels
- Fecal calprotectin: indicates colonic inflammation (3)
- Stool studies to rule out infectious cause: Clostridium difficile toxin (four samples), stool cultures, Shiga toxin, ova and parasite microscopy, Giardia antigen
- Sexually transmitted infection testing to rule out proctitis, particularly in men who have sex with men: chlamydia, gonorrhea, herpes simplex virus, syphilis (3)
- Perinuclear antineutrophil cytoplasmic antibody (pANCA) and anti-Saccharomyces cerevisiae antibodies (ASCA) are commonly present in patients with UC, but testing for these is not currently recommended for diagnosis (3).
- Abdominal x-ray to exclude dangerous colonic dilation and assess disease severity (3)

**Diagnostic Procedures/Other**
- Colonoscopy with at least two biopsies from each of five sites along the entire colon is an initial diagnostic step to confirm colitis (3).
- Complete colonoscopy in severe UC may be contraindicated due to risk of perforation or precipitation of toxic megacolon (3).

**Test Interpretation**
- Endoscopic findings that support UC include mucosal engorgement with vascular markings, mucosal erythema, and mucosal granularity. Affected areas will extend proximally and continuously.
- Histologic findings that support UC include mucosal separation, distortion, and atrophy of the crypts; chronic inflammatory cells in lamina propria; lymphocytes and plasma cells in crypt bases (2)[C].
- If only rectal biopsy, villous mucosal architecture and Paneth cells metaplasia support UC (2)[C].
- Mild ileal inflammation (“backwash ileitis”) may be present in UC (2)[C].
**TREATMENT**

Treatment strategies are determined by functional status, degree of colonic involvement, course of illness, frequency of relapses, extraintestinal manifestations, response to prior treatments, and side effect profile.

**MEDICATION**

**First Line**
- Proctitis/distal colitis with mild or moderate severity: 5-ASA (e.g., mesalamine 1 g/day) suppository; 5-ASA foam enemas are an alternative but less effective (4)[C].
- Left-sided UC with mild to moderate severity: topical 5-ASA (e.g., mesalamine 1 g/day) and >2 g/day oral mesalamine (4)[C]
- Left-sided severe UC: hospital admission and systemic steroids (e.g., prednisone 40 to 60 mg/day) and mesalamine/5-ASA (4)[C]
- Extensive UC of mild to moderate severity: oral sulfasalazine titrated up to 4 to 6 g/day or a combination of topical and oral 5-ASA (above) (4)[C]
- Severe UC: necessitates hospitalization for intensive treatment and surveillance for complications; IV steroids (methylprednisolone 60 mg/day or hydrocortisone 400 mg/day) with or without 2 to 6 g/day oral mesalamine (4)[C]

**Second Line**
- Proctitis/distal colitis with mild to moderate severity: first-line therapy and 2 to 6 g/day oral mesalamine. Topical corticosteroids (budesonide 2 to 8 mg/day or hydrocortisone 100 mg/day) may be added (4)[C].
- Left-sided UC with mild to moderate severity: first-line therapy and topical corticosteroids (budesonide 2 to 8 mg/day or hydrocortisone 100 mg/day) may be added. Persistent rectal bleeding despite this regimen can be treated with systemic prednisone at 40 to 60 g/day with a prolonged taper (4)[C].
- Left-sided severe UC: first-line therapy and prednisone at 40 to 60 g/day and long taper; if refractory, azathioprine 2.5 mg/kg/day or 6-mercaptopurine (1.5 mg/kg/day) for induction and maintenance (4)[C]
- Severe UC: TNF-α-blocker IFX (adalimumab, infliximab, golimumab) combined with methotrexate or thiopurine. Patients with severe UC will often need timely colectomy (4)[C].
- Infliximab adult dose: 5 mg/kg IV at weeks 0, 2, and 6 for induction and then maintenance of 5 mg/kg IV is given every 8 weeks.
- Adalimumab: dose: 160 mg SC (given as four injections on day 1 or two injections daily over 2 consecutive days; limit injections to 40 mg per injection); second dose 2 weeks later: 80 mg; and maintenance: 40 mg every other week (5)[C]
- Other second-line therapies, particularly in refractory disease, include CsA 4 mg/kg/day and tacrolimus 0.1 to 0.2 mg/kg/day PO or 0.01 to 0.02 mg/kg/day IV. Trough concentrations with tacrolimus should be 10 to 15 ng/mL.
- TNF-α-blockers can help maintain remission in steroid-dependent patients with severe UC.
- Immunosuppressive therapy increases risk of opportunistic infections. Chronic steroid use can cause adrenal suppression, gastrointestinal bleeding, heart disease, osteoporosis, thinning of skin, and compromised vascular wall integrity. Infusion of biologics carries the risk of anaphylactic reactions during treatment.
Pediatric Considerations
Pediatric growth and development can be affected due to malabsorption.

SURGERY/OTHER PROCEDURES
- Surgery is indicated for medically refractory disease (particularly with high-dose steroids).
- Emergent surgery (typically total or subtotal abdominal colectomy with end ileostomy) for massive hemorrhage, perforation, and toxic dilatation
- Total colectomy with ileostomy is curative.
- Total proctocolectomy with ileal pouch anal anastomosis (IPAA) is the most common surgery and an appropriate alternative to ileostomy. Common complications include pouchitis (50%) and need for reoperation in up to 30% (2)[C].

COMPLEMENTARY & ALTERNATIVE MEDICINE
- There is ongoing research into the role of probiotics, dietary changes, and fecal microbiota transplant as treatment for UC. The current evidence is insufficient to support the efficacy of any particular alternative therapy for achieving or maintaining remission.
- Tobacco cessation is associated with 65% reduction in relapse (3)[C].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admission for UC or its complications warrants gastroenterology consultation.
- Severe UC may require emergent surgical intervention. Consultation with surgery is indicated.
- Imaging studies help assess disease activity and colon size.
- Initiate IV corticosteroids and rule out infectious etiologies (C. difficile, cytomegalovirus, Shigella/Amoeba).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Regular surveillance colonoscopy in patients with prolonged (8 to 10 years) active disease (2)
- Initiate annual surveillance immediately in patients with primary sclerosing cholangitis.
- Annual LFTs and cholangiography for cholestasis
- Annual BUN/creatinine for patients on long-term mesalamine

Pediatric Considerations
Cumulative risk of cancer increases with duration of disease. Ensure regular surveillance.

DIET
- NPO during acute exacerbations
- There are otherwise no specific dietary recommendations. Dietary research is ongoing.

PATIENT EDUCATION
Crohn’s and Colitis Foundation of America (CCFA): http://www.ccfa.org/

PROGNOSIS
- Chronic disease with variable severity and rate of recurrence
- Variable; mortality for initial attack is ~5%; 75–85% experience relapse; up to 20% require
Colon cancer risk is the single most-important factor affecting long-term prognosis. Left-sided colitis and ulcerative proctitis have favorable prognoses with probable normal lifespan.

**Geriatric Considerations**
- Increased mortality if first presentation occurs after 60 years of age
- Consider lower medication dosages and slower titration due to risks of polypharmacy.

**COMPLICATIONS**
- Perforation: Treat toxic megacolon with prompt surgery. Limit colonoscopies in severe disease.
- Obstruction
- Anemia
- Fulminant colitis
- Toxic megacolon
- Liver disease
- Stricture formation
- Osteoporosis
- Colorectal cancer

Algorithm: Hematemesis (Bleeding, Upper Gastrointestinal)
CODES

ICD10

- K51.90 Ulcerative colitis, unspecified, without complications
- K51.919 Ulcerative colitis, unspecified with unspecified complications
- K51.80 Other ulcerative colitis without complications

CLINICAL PEARLS

- Diffuse, uninterrupted colonic mucosal inflammation
- Hallmark symptom is bloody diarrhea.
- Annual or biannual surveillance colonoscopy after 8 to 10 years of colitis due to increased risk of colorectal cancer
URETHRITIS
Danielle Taylor, DO ● Cynthia D. Hall, MD

BASICS

DESCRIPTION
● Inflammation of the urethra
● Common manifestation of sexually transmitted infection (STI)
● Frequently associated with dysuria, pruritus, and/or urethral discharge; classified as gonococcal (caused by Neisseria gonorrhoeae) and nongonococcal (caused by other bacteria, or less commonly autoimmune disorders [Reiter syndrome], trauma, or chemical irritation)

EPIDEMIOLOGY

Incidence
● In 2016, there were 468,514 reported cases of gonorrhea, with a rate of 146 cases per 100,000 per population (18.5% rate increase since 2015) (1).
● In 2016, there were 1,598,354 reported cases of Chlamydia trachomatis infection or 497 cases per 100,000 per population (17.6% rate increase since 2015) (1).
● Chlamydia is the most commonly reported STD (1).
● Rate of chlamydial infection in U.S. women was more than twice that of men, reflecting higher rates of screening (1).
● Highest incidences of gonorrhea and chlamydia among young men and women, ages 15 to 24 years (>50% of all cases) (1)
● Chlamydial infections are 5 times more likely in young adult women than gonococcal infections (1).

ETIOLOGY AND PATHOPHYSIOLOGY
● Most common cause is infection via sexual transmission of N. gonorrhoeae, a gram-negative diplococcus.
● N. gonorrhoeae is a gram-negative diplococcus which interacts with nonciliated epithelial cells → cellular invasion → inflammation, neutrophil production, bacterial cell phagocytosis (2).
● Sexually transmitted C. trachomatis infection is the most common cause of nongonococcal urethritis.
● Other established pathogens:
  – Mycoplasma genitalium
  – Trichomonas vaginalis
  – Ureaplasma urealyticum
  – Herpes simplex virus (rare)
  – Adenovirus (rare)
● Noninfectious causes (less common)
  – Chemical irritants (i.e., soaps, shampoos, douches, spermicides)
  – Foreign bodies
  – Urethral instrumentation

RISK FACTORS
● Age 15 to 24 years
- New sex partner
- One or more sex partner(s)
- History of or coexisting STI
- Sex partner with concurrent partner(s)
- Inconsistent condom use outside of a mutually monogamous relationship
- Exchanging sex for money or drugs
- Member of population with increased prevalence of infection, including incarcerated populations, military recruits, and economically disadvantaged populations

**GENERAL PREVENTION**
- Use of male condoms, female condoms, or cervical diaphragms
- Abstinence or reduction in the number of sex partners
- Behavioral counseling

**COMMONLY ASSOCIATED CONDITIONS**

**ALERT**
Annual chlamydia and gonorrhea screening is recommended for all sexually active women <25 years, women >25 years with risk factors, and all men who have sex with men. There is insufficient evidence to recommend testing all men <25 year (3)[A].

**DIAGNOSIS**
- **Chief complaint**
  - Urethral discharge (mucopurulent suggestive of N. gonorrhoeae)
  - Dysuria
  - Erythema of the urethral meatus
  - Symptom onset 2 to 8 days following exposure
- **History**
  - Sexual history, including condom use, number of partners, sexual behaviors
  - Previous STIs
  - Substance abuse
  - Recent travel
  - Symptoms indicative of complications or additional sites of infection (i.e., men: testicular pain and swelling, anal itching, rectal pain or bleeding; women: lower abdominal pain, dyspareunia, irregular vaginal bleeding)
- **Male GU exam (possible findings)**
  - Urethral discharge
  - Meatal erythema
  - Testicular tenderness
  - Palpate scrotum to check for epididymitis or orchitis.
  - Assess for ulcers.
  - Assess for inguinal lymphadenopathy.
- **Female genitourinary (GU) exam (possible findings)**
  - Vaginal discharge
  - Endocervical discharge, hyperemia, and/or friability
**Pediatric Considerations**
Pediatric infections with gonorrhea and chlamydia after the neonatal period strongly suggest sexual contact. If indicated, investigations should be initiated promptly (4).

**DIFFERENTIAL DIAGNOSIS**
- Other GU tract diseases
  - Cystitis/urinary tract infection
  - Epididymitis
  - Prostatitis
  - PID
  - Pyelonephritis
- Vaginal atrophy, especially in postmenopausal women
- Stevens-Johnson syndrome
- Reiter syndrome: uveitis, urethritis, arthritis
- Wegener granulomatosis
- Urethral syndrome (pain without infection or purulence), longstanding or intermittent symptoms

**DIAGNOSTIC TESTS & INTERPRETATION**

**ALERT**
Health care providers are required to report all gonorrhea and chlamydia infections in accordance with local and state requirements.

**Initial Tests (lab, imaging)**
- **Gonorrhea**
  - Nucleic acid amplification test (NAAT)
  - Sensitivity: 90–100%
  - Specificity: 97–100%
  - Preferred specimen collection in first void (men) and vaginal swab (women)
  - Tissue culture was the traditional gold standard but typically only used now in cases of suspected treatment resistance (4).
- **Chlamydia**
  - NAAT
  - Sensitivity: 85–95%
  - Specificity: 93–99%
  - Preferred specimen collection is same as for gonorrhea.
  - Tissue culture was the traditional gold standard but currently NOT recommended (4).
- **Gram stain diagnosis criteria**
  - Urethral secretions with ≥2 WBC per oil immersion
  - Mucopurulent or purulent discharge
  - First void urine sediment with ≥10 WBC per high power field (4)
  - Symptom onset 2 to 8 days following exposure
- **Methylene blue/gentian violet [MB/GV]**
  - Alternative to gram staining
  - Does not require heat fixation
  - Sensitivity: 97.3% (same as gram stain)
- If concern for Trichomonas: NAAT (urine, urethral, vaginal, or endocervical swab), wet
mount, or culture

- There is no FDA-approved diagnostic test available for M. genitalium, an emerging pathogen with a greater prevalence than gonorrhea in many populations (5).

**ALERT**
Due to the similarity in clinical symptoms and high rates of coinfection, cotesting for gonorrhea and chlamydia infection is recommended. In addition, given that risk factors for gonorrhea and chlamydia indicate risks for other STIs, screening for HIV, RPR, hepatitis C, and hepatitis B may also be indicated.

**Follow-Up Tests & Special Considerations**
- Test of cure (TOC) for chlamydia and gonorrhea is recommended in pregnant women or when treatment noncompliance is suspected (4).
- Repeat testing in 3 months recommended due to rates of reinfection (4)
- HIV infection: Persons with HIV infection should receive the same treatment as patients without HIV infection (4).

**Diagnostic Procedures/Other**
Urethrocystoscopy for cases with suspected foreign body, intraurethral warts, urethral stricture

**Test Interpretation**
Urethral strictures (untreated gonorrhea), intraurethral lesions (venereal warts, congenital anomalies), PID, or tubo-ovarian abscesses are possible.

**TREATMENT**
- Most cases can be treated in the outpatient setting.
- Single-dose regimens with direct observation preferred (4)

**MEDICATION**
**CDC recommendations**
- Chlamydia
  - First line
    - Azithromycin 1 g PO × 1 dose
    - OR
    - Doxycycline 100 mg PO BID for 7 days (3)[A]
  - Alternate regimens (all for 7 days)
    - Erythromycin base 500 mg PO QID
    - Erythromycin ethylsuccinate 800 mg PO QID
    - Levofloxacin 500 mg daily
    - Ofloxacin 300 mg PO BID
  - Second line (all for a duration of 7 days)
    - Erythromycin base 500 mg PO QID
    - Erythromycin ethylsuccinatated 800 mg PO QID
    - Levofloxacin 500 mg daily
    - Ofloxacin 300 mg PO BID
- Gonorrhea
First line
- Ceftriaxone 250 mg IM plus either
  - Azithromycin 1 g PO × 1 dose (preferred)
  - Doxycycline 100 mg PO BID × 7 days
  - For children ≤45 kg
    - Ceftriaxone 25 to 50 mg/kg IM × 1 dose
  - For children >45 kg, use adult dosing.
- Second line
  - Cefixime 400 mg IM plus either
    - Azithromycin 1 g PO × 1 dose (preferred)
    - Doxycycline 100 mg PO BID × 7 days
  - TOC in 1 week

Trichomonas
- Metronidazole 2 g PO × 1 dose

Recurrent and persistent urethritis
- If azithromycin was initially used, moxifloxacin 400 mg PO QD × 7 days
- If doxycycline was initially used, azithromycin 1 g PO × 1 dose

General considerations
- Contraindications: sensitivity to any of the indicated medications
- Precautions: Patients taking tetracyclines may have increased photosensitivity.
- Significant possible interactions
  - Tetracyclines should not be taken with milk products or antacids.
  - Oral contraceptives may be rendered less effective by oral antibiotics. Patients and partners should use a back-up method of birth control for the remainder of the cycle.

Pregnancy Considerations
- Chlamydia:
  - Screen all pregnant patients.
  - All pregnant women at increased risk should be screened for chlamydia at their prenatal visit and again in the 3rd trimester.
  - TOC 3 weeks after therapy to check for chlamydial eradication and retest in 3 months
  - Azithromycin 1 g PO × 1 dose

  Alternative regimens:
  - Amoxicillin 500 mg TID × 7 days
  - OR
  - Erythromycin 500 mg QID × 7 days

- Gonorrhea:
  - Screen all pregnant patients.
  - All pregnant women at increased risk should be screened for chlamydia at their prenatal visit and again in the 3rd trimester.
  - TOC 3 weeks after therapy to check for gonococcal eradication and retest in 3 months
  - Tetracyclines and quinolones are contraindicated.
  - Dual therapy treatment
    - Ceftriaxone 250 mg IM × 1 dose
Azithromycin 1 g PO × 1 dose
– If cephalosporin allergy and spectinomycin is not available, infectious disease consult is recommended.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Sexual activity should be avoided for 7 days following administration of single-dose therapy or until completion of multiday regimen.
- All sexual partners who came in contact with the patient within 60 days should be referred for evaluation, testing, and presumptive treatment (4).
- Expedited partner therapy (EPT) is an acceptable alternative; EPT—the practice of treating the diagnosed patient’s sex partner(s) for chlamydia or gonorrhea by providing medications to the partner(s) without clinical evaluation (4).

**Patient Monitoring**
- Instruct patients to return if symptoms persist or recur after completing treatment.
- Screen for reinfection in all patients at 3 months.

**PATIENT EDUCATION**
- Behavioral counseling interventions are recommended. Evidence of benefit increase with intensity of intervention (6,7)[B].
- Successful approaches include basic information about STIs and transmission, assess risk for transmission, include training skills (i.e., condom use, communication about safe sex, problem solving, goal setting) (7).

**PROGNOSIS**
If the diagnosis is firmly established, appropriate medications are prescribed and the patient is compliant with treatment; relief of symptoms occurs within days, and the problem will resolve without sequela.

**COMPLICATIONS**
- Stricture formation
- Epididymitis
- Prostatitis
- PID in women
- Disseminated gonococcal infection
- Gonococcal meningitis
- Gonococcal endocarditis
- Perinatal transmission (chlamydial conjunctivitis, chlamydial pneumonia, ophthalmia neonatorum)
- Reiter syndrome
- Chronic cervical chlamydial infection has been proposed to increase risk of cervical cancer (8).

CODES

ICD10

- N34.2 Other urethritis
- A56.01 Chlamydial cystitis and urethritis
- A54.01 Gonococcal cystitis and urethritis, unspecified

CLINICAL PEARLS

- Inflammation of the urethra, frequently associated with dysuria, pruritus, and/or urethral discharge
- Common manifestation of STI
- Classified as gonococcal (caused by N. gonorrhoeae) and nongonococcal
- NAAT preferred method of diagnosis for men and women
- Single-dose regimens with direct observation preferred
- In cases of gonorrhea or chlamydia infection, in person or EPT recommended for all partners of patients within the last 60 days
- Given that risk factors for gonorrhea and chlamydia indicate risk for other STIs, screening for HIV, RPR, hepatitis C, and hepatitis B may also be indicated.
- Repeat testing for gonorrhea and chlamydia in 3 months recommended due to rates of reinfection.
- Special considerations in pediatric and pregnant populations
- Treatment in persons with HIV infection is the same as in patients without HIV infection.
- Health care providers are required to report all gonorrhea and chlamydia infections in accordance with local and state requirements.
URINARY TRACT INFECTION (UTI) IN FEMALES
Akhil Das, MD, FACS ● May Jean Counsilman, MD

BASICS

DESCRIPTION
- Urinary tract infection (UTI) is the presence of pathogenic microorganisms within the urinary tract with concomitant symptoms.
- This topic refers primarily to acute infectious cystitis; other complicated UTIs, such as pyelonephritis, are discussed elsewhere.
- Uncomplicated UTI: occurs in patients who have a normal, unobstructed urinary tract, who have no history of recent urologic procedure, and whose symptoms are confined to the lower urinary tract. Uncomplicated UTIs are most common in young, sexually active women.
- Complicated UTI: an infection of the lower or upper urinary tract in the presence of an anatomic abnormality, a functional abnormality, or compromised host (see “Risk Factors”)
- Recurrent UTI: symptomatic UTIs that follow resolution of an earlier episode after appropriate treatment
  - Three UTIs within 12 months or two within 6 months
  - Most recurrences are thought to represent reinfection rather than relapse.
  - No evidence indicates that recurrent UTIs lead to health problems such as hypertension or renal disease in the absence of anatomic or functional abnormalities of the urinary tract.
- System(s) affected: renal, urologic
- Synonym(s): cystitis

EPIDEMIOLOGY

Incidence
- Accounts for 8 million doctor visits and 1 million emergency room visits and contributes to >100,000 hospital admissions each year
- 11% of women have UTIs in any given year.
- Predominant age: young adults and older
- Predominant sex: female > male

Prevalence
- >50% of females have at least one UTI in their lifetime.
- One in four women has recurrent UTIs.
- 1/4 of women with uncomplicated UTI experience a second UTI within 6 months and 1/2 at some time during their lifetime.

ETIOLOGY AND PATHOPHYSIOLOGY
- Bacteria and subsequent infection in the urinary tract arise chiefly via ascending bacterial movement and propagation (1).
- Pathogenic organisms (Escherichia coli) possess adherence factors and toxins that allow initiation and propagation of genitourinary infections:
  - Type 1 and P. pili (pyelonephritis-associated pili)
  - Lipopolysaccharide
- Most UTIs are caused by bacteria originating from bowel flora:
- E. coli is the causative organism in 80% of cases of uncomplicated cystitis.
- Staphylococcus saprophyticus accounts for 15% of infections.
- Enterobacteriaceae (i.e., Klebsiella, Proteus, Enterobacter, and Pseudomonas) also contribute.
- Candida is associated with nosocomial UTI (1).

**Genetics**
Women with human leukocyte antigen 3 (HLA-3) and nonsecretor Lewis antigen have an increased bacterial adherence, which may lead to an increased risk in UTI.

**RISK FACTORS**
- Previous UTI
- Diabetes mellitus (DM)
- Pregnancy
- Sexual activity
- Use of spermicides or diaphragm
- Underlying abnormalities of the urinary tract such as tumors, calculi, strictures, bladder diverticula, incomplete bladder emptying, urinary incontinence, neurogenic bladder
- Catheterization
- Recent antibiotic use
- Poor hygiene
- Estrogen deficiency
- Inadequate fluid intake

**GENERAL PREVENTION**
- Maintain good hydration.
- Women with frequent or intercourse-related UTI should empty bladder immediately before and following intercourse; consider postcoital antibiotic.
- Avoid feminine hygiene sprays and douches.
- Wipe urethra from front to back.
- Cranberry tabs may prevent recurrent infections.
- Vaginal estrogen in postmenopausal women may prevent infection.

**COMMONLY ASSOCIATED CONDITIONS**
See “Risk Factors.”

**Geriatric Considerations**
- Elderly patients are more likely to have underlying urinary tract abnormality or voiding dysfunction.
- Acute UTI may be associated with incontinence or mental status changes in the elderly.
- Asymptomatic bacteriuria is very common in the elderly and should not be confused for infection and should not be treated. Treatment does not improve outcomes and may cause morbidity.

**Pediatric Considerations**
Pediatric patients are more likely to have bowel bladder dysfunction or congenital urinary tract abnormalities such as vesicoureteral reflux or a duplicated collecting system.
DIAGNOSIS

HISTORY
Note: Any or all may be present:
- Burning or pain during urination (dysuria)
- Urgency (sensation of need to urinate often)
- Frequency
- Sensation of incomplete bladder emptying
- Blood in urine
- Lower abdominal pain or cramping
- Offensive odor of urine
- Nocturia
- Sudden onset of urinary incontinence
- Dyspareunia

PHYSICAL EXAM
- Suprapubic tenderness
- Urethral and/or vaginal tenderness
- Fever or costovertebral angle tenderness indicates upper UTI (pyelonephritis).

DIFFERENTIAL DIAGNOSIS
- Vaginitis
- Asymptomatic bacteriuria
- STDs causing urethritis or pyuria
- Hematuria from causes other than infection (e.g., neoplasia, calculi)
- Interstitial cystitis
- Psychological dysfunction

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- No lab testing is necessary in women with high likelihood of lower UTI based on classic symptoms. Negative dipstick in the presence of high pretest probability does not rule out UTI.
- Urinalysis (microscopic)
  - Pyuria (>10 neutrophils/high-power field [HPF])
  - Bacteriuria (any amount on unspun urine or five bacteria/HPF on centrifuged urine)
  - Hematuria (≥3 RBCs/HPF)
- Dipstick urinalysis
  - Leukocyte esterase (75–96% sensitivity, 94–98% specificity, when >100,000 colony-forming units [CFU])
  - Nitrite tests are useful with nitrite-reducing organisms (e.g., E. coli, Klebsiella, Proteus).
- Urine culture: only indicated if diagnosis is unclear or patient has recurrent infections and resistance is suspected. It is neither cost-effective nor usually helpful for lower tract, uncomplicated UTI.
  - Presence of 100,000 CFU/mL of organism indicates infection.
  - Identification of a single organism at lower CFU per milliliter likely also represents infection in the presence of appropriate symptoms.
  - Suspect a contaminated specimen when culture shows multiple types of bacteria.
Utility and use of molecular diagnostics for detection of bacteria does not have sufficient evidence and cannot be recommended at this time.

Imaging studies are often not required in most cases of UTI.

Follow-Up Tests & Special Considerations

- In nonpregnant, premenopausal women with symptoms of UTI, positive urinalysis, and no risks for complicated infection, empirical treatment may be given without obtaining a urine culture.
- Imaging may be indicated for UTIs in men, infants, immunocompromised patients; for febrile infection; for signs or symptoms of obstruction; for failure to respond to appropriate therapy; and in patients with recurrent infections.
- CT scan and magnetic resonance imaging provide the most complete anatomic data in adults but should be utilized only when appropriate.

Pediatric Considerations

For infants and children, obtain renal bladder ultrasound; if pelvocalyctasis or ureteral dilatation is detected, consider obtaining a voiding cystourethrogram to evaluate for vesicoureteral reflux.

Diagnostic Procedures/Other

- Urethral catheterization may be necessary to obtain a urine specimen from children and adults if the voided urine is suspected of being contaminated.
- Suprapubic bladder aspiration or urethral catheterization techniques can be used to obtain specimens from infants.
- Cystourethroscopy can be used to evaluate patients with recurrent complicated UTIs, previous anti-incontinence surgery, or hematuria in the absence of an active infection.

TREATMENT

GENERAL MEASURES

- Asymptomatic bacteriuria in a nonpregnant woman should not be treated with antibiotics (2) [C].
- Maintain good hydration especially in those consuming less than 1.5 L water per day.
- Maintain good hygiene.
- Many women with uncomplicated UTI clear symptoms without treatment and rarely progress to more severe disease.

MEDICATION

First Line

- The urinary tract topical analgesic phenazopyridine 100 to 200 mg TID produces rapid relief of symptoms and should be offered to patients with more than minor discomfort; it is available over the counter. This medication is not a substitute for definitive treatment and may alter urinalysis (presents as nitrite positive) but not the urine culture.
- Choice of antibiotic should be made with consideration to patient allergy, compliance, local resistance patterns, availability, and cost.
- Uncomplicated UTI (adolescents and adults who are nonpregnant, nondiabetic, afebrile, immunocompetent, and without genitourinary anatomic abnormalities)
  - Trimethoprim/sulfamethoxazole (TMP/SMX; Bactrim): 160/800 mg PO BID for 3 days,
best where resistance of E. coli strains <20%. Rash may be higher than with other antibiotics. Preferred 1st line
  – Nitrofurantoin (Macrobid): 100 mg PO BID for 5 days should be used in patients with allergy to TMP/SMX and in areas where E. coli resistance to TMP/SMX >20%. A preferred 1st line antibiotic.
  – Fosfomycin (Monurol): 3 g PO single dose (expensive)
  
- **Lower UTI in pregnancy**
  – Nitrofurantoin (Macrobid): 100 mg PO BID for 7 days
  – Cephalexin (Keflex): 500 mg PO BID for 7 days
  – TMP/SMX use in pregnancy is not desirable (especially in 1st and 3rd trimester) but is appropriate in some circumstances.
  – Fluoroquinolones are not safe during pregnancy and are usually avoided in treatment of children.

- **Postcoital UTI:** Single-dose TMP/SMX or cephalexin may reduce frequency of UTI in sexually active women.

- **Complicated UTI** (pregnancy, diabetes, febrile, immunocompromised patient, recurrent UTIs): Extend course to 7 to 10 days of treatment with antibiotic chosen based on culture results; may begin with fluoroquinolone, TMP/SMX, or cephalosporin while awaiting results (avoid using nitrofurantoin for complicated UTI due to lack of tissue penetration)

### Second Line

- **Uncomplicated UTI**
  – β-Lactams (amoxicillin/clavulanate, cefdinir, cefpodoxime proxetil) for 3 to 7 days
  – Fluoroquinolones are effective but should not be used in uncomplicated UTI due to risk of serious and potentially irreversible adverse reactions (see FDA black box warnings regarding hypoglycemia, tendon rupture risk, neurologic problems including neuropathy).

- **Chronic UTIs**
  – Women with recurrent UTIs can be treated with a number of different strategies. Some authors suggest continuous antibiotics (3). Treatment duration is guided by the severity of patient symptoms and by physician and patient preference: Consider 3 to 6 months of daily therapy, followed by observation for reinfection after discontinuing prophylaxis.
  – Continuous antimicrobial prophylaxis involves daily administration of low-dose TMP/SMX 80/400 mg or nitrofurantoin 50 to 100 mg, among others.
  – Other options are patient-initiated treatment for early UTI sx, post-coital prophylaxis (for those whose UTIs follow sex), and intermittent-dosed prophylaxis (e.g., Monday-Wednesday-Friday)
  – Other authors note that patient self-initiated treatment does not reduce number of UTI episodes, but compared with prophylactic strategies or physician-initiated treatment, this approach minimizes the physiologic and financial cost of frequent antibiotic use, cost of diagnosis, number of physician visits, and number of symptomatic days by limiting doses to symptomatic events.

### Pediatric Considerations

Long-term antibiotics appear to reduce the risk of recurrent symptomatic UTI in susceptible children, but the benefit is small and must be considered together with the increased risk of microbial resistance.
ISSUES FOR REFERRAL
- Patients with recurrent or complicated UTIs should be referred to a urologist for evaluation.

Pediatric Considerations
UTI in children, especially <1 year of age, should prompt referral to a pediatric urologist and workup for urinary tract anomalies.

SURGERY/OTHER PROCEDURES
- Urinary tract obstruction with sepsis from a urinary source requires urgent drainage of the obstructed system with cystoscopy and ureteral stent or a percutaneous nephrostomy tube.
- Patients with emphysematous pyelonephritis or pyonephrosis may need immediate surgical intervention.

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Preliminary studies indicate that Vaccinium macrocarpon (cranberry, not cranberry juice cocktail) may help to prevent and treat UTIs by inhibiting bacterial adherence to the bladder epithelium. It may decrease the number of symptomatic UTIs over a 1-year period.
- Methenamine (Hiprex) can be used for recurrent UTIs (converts to formaldehyde in urine).
- Vaginal estrogen can be used to prevent recurrent UTIs in peri- and post-menopausal women.
- Other complementary therapies, such as urine alkalinization, acupuncture, and oral or vaginal vaccines appear to be attractive alternatives for prevention of UTIs; however, there is a lack of head-to-head trials to support their use.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Inpatient evaluation is reserved for patients with complicated or upper tract UTIs. Majority of UTIs are managed in an outpatient setting.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- First or rare UTI: Young or middle-age, nonpregnant adult females require no follow-up if UTI is clinically cured after 3-day therapy (2)[C].
- If symptoms persist after 2 to 3 days of therapy, obtain culture/sensitivity and change antibiotic accordingly.

Pregnancy Considerations
- UTI during pregnancy always requires culture/sensitivity and usually requires a 7- to 14-day treatment.
- Following the treatment of acute infection, pregnant women warrant surveillance urine cultures every trimester. They may receive prophylactic antibiotics for the remainder of pregnancy for recurrent or upper tract disease.

DIET
Proper dietary glucose control in diabetic patients can help reduce the frequency of UTIs.

PATIENT EDUCATION
- Although no controlled studies support this intervention, postcoital voiding is commonly advised.
PROGNOSIS
Symptoms resolve within 2 to 3 days of antibiotic treatment in almost all patients.

COMPLICATIONS
- Pyelonephritis or sepsis
- Renal abscess
- Acute urinary outlet obstruction

Pregnancy Considerations
Pregnant females, infants, and young children with cystitis are at higher risk of pyelonephritis.

REFERENCES

SEE ALSO
Algorithm: Dysuria

CODES
ICD10
- N39.0 Urinary tract infection, site not specified
- N30.90 Cystitis, unspecified without hematuria
- N30.91 Cystitis, unspecified with hematuria

CLINICAL PEARLS
- Uncomplicated lower UTIs cause significant short-term morbidity but generally do not cause renal damage.
- Culture is generally not indicated for women with symptoms of uncomplicated UTI.
- Treatment of uncomplicated UTIs reduces morbidity but does not reduce risk of recurrence.
- Uncomplicated UTIs should be treated for 3 days (TMP/SMX) or 5 days (nitrofurantoin). All pregnant women with bacteriuria should be treated.
- Health care professionals should not treat women with asymptomatic bacteriuria with antibiotics (except pregnant patients).
- Fluoroquinolones should be reserved for complicated UTI.
BASICS

DESCRIPTION
- Cystitis is an infection of the lower urinary tract, usually resulting from a single gram-negative enteric bacteria (see also “Prostatitis,” “Pyelonephritis,” and “Urethritis”).
- System(s) affected: renal/urologic
- Synonym(s): urinary tract infection (UTI); cystitis
- In otherwise healthy males ages 15 to 50 years, UTI is uncommon and considered uncomplicated.
- In male newborns, infants, and elderly men UTI is considered complicated, with associated functional/structural mechanisms.

EPIDEMIOLOGY

Incidence
- Approximately 20% of UTIs occur in men.
- Predominant age: increases with age
- Uncommon in men <50 years of age
- 6 to 8 infections per 10,000 men aged 21 to 50 years (1)

Prevalence
- Lifetime prevalence approximately 14%

ETIOLOGY AND PATHOPHYSIOLOGY
- Escherichia coli (majority of infections)
- Klebsiella
- Enterobacter
- Enterococcus
- Proteus
- Citrobacter
- Providencia
- Streptococcus faecalis and Staphylococcus sp.
- Pseudomonas and Morganella (more common in elderly and catheterized patients)
- Pathogenesis—bacterial entry into urinary tract via ascension or bladder instrumentation

Genetics
- Not applicable

RISK FACTORS
- Age
- Obesity
- History of prior UTI
- Outlet obstruction
  - Benign prostatic hypertrophy (BPH)—incidence of 33% of men with UTIs (2)
- Urethral stricture
- Calculi
- Fecal incontinence
- Urinary incontinence
- Recent urologic surgery
- Urinary tract instrumentation/catheterization
- Infection of the prostate/kidney
- Immunocompromised
- Diabetes
- Bladder diverticula
- Neurogenic bladder
- Cognitive impairment
- Institutionalization
- Uncircumcised
- Anal intercourse
- Intercourse with an infected female partner (1)

**GENERAL PREVENTION**
- Prompt treatment of predisposing factors
- Use a catheter only when necessary; if needed, use aseptic technique and closed system and remove as soon as possible.
- Cranberry products are not recommended for preventing UTI.

**COMMONLY ASSOCIATED CONDITIONS**
- Acute bacterial pyelonephritis
- Chronic bacterial pyelonephritis
- Urethritis
- Prostatitis
- Prostatic hypertrophy
- Prostate cancer

**Geriatric Considerations**
Bacteriuria is more common among the elderly, usually is transient, and may be related to functional status. Of men >65 years of age, 5–10% have asymptomatic bacteriuria (ASB). If ASB is noted, no treatment is needed (3,4).

**Pediatric Considerations**
Can be associated with obstruction to normal flow of urine, such as vesicoureteral reflux. Unique diagnostic criteria and evaluation recommendations exist (see below).

**DIAGNOSIS**

**HISTORY**
- Urinary frequency
- Urinary urgency
- Dysuria
- Hesitancy
- Slow urinary stream
- Dribbling of urine
- Nocturia
- Suprapubic discomfort or perineal pain
- Low back pain
- Hematuria
- Systemic symptoms (chills, fever) or flank pain, nausea, vomiting present with concomitant pyelonephritis or prostatitis

**PHYSICAL EXAM**
- Suprapubic tenderness
- Costovertebral angle (CVA) tenderness and/or fever may be present with concomitant pyelonephritis/prostatitis/epididymitis.
- Perform genital examination.
- Consider digital rectal exam, including palpation of the prostate gland, to rule out bacterial prostatitis.

**DIFFERENTIAL DIAGNOSIS**
- Anatomic/functional pathology of the urinary tract
- Urethritis/sexually transmitted infections (STIs)
- Infections in other sites of the genitourinary tract (e.g., epididymitis, prostatitis). >90% of men with febrile UTI have concomitant prostate infection (1)[A].

**DIAGNOSTIC TESTS & INTERPRETATION**
- Urine dipstick/manual microscopy of clean catch midstream void showing the following:
  - Pyuria (>10 WBCs)
  - Bacteriuria
  - Leukocyte esterase is more sensitive, and nitrite is more specific in detecting UTI (5).
  - Positive leukocyte esterase (in males: sensitivity, 78%; specificity, 59%; positive predictive value [PPV], 71%; negative predictive value [NPV], 67%)
  - Positive nitrite (in males: sensitivity, 47%; specificity, 98%; PPV, 96%; NPV, 59%)
- Automated microscopy/flow cytometry that measures cell counts and bacterial counts can be used to improve screening characteristics (sensitivity, 92%; specificity, 55%; PPV, 47%; NPV, 97%). The high NPV of these screening tests allows for more judicious use of urine culture (5) [B].
- Urine culture: >100,000 colony-forming units (CFU; >10^5 CFU) of bacteria/mL of urine confirm diagnosis.
- Lower counts, such as >10^3 CFU, also may be indicative of infection, especially in the presence of pyuria.
- Diagnosis in infants and children <24 months made on the basis of both pyuria and 50,000 CFU on culture
- Renal and bladder ultrasound recommended in infants and young children after first confirmed UTI

**Follow-Up Tests & Special Considerations**
- Consider assessing for risk factors for STIs because chlamydial/gonococcal urethritis can mimic a UTI. If risk factors are present, use urine nucleic acid amplification tests to identify
gonococcal and Chlamydia infections and treat as necessary.

- Further urologic evaluation is warranted to rule out other disorders in men with recurrent UTI, febrile UTI, or pyelonephritis. This may include the following:
  - Ultrasound
  - Cystoscopy
  - Urodynamics
  - IV pyelography
- Value of a urologic evaluation in a single uncomplicated UTI has not been determined.
- Antibiotics prior to culture or phenazopyridine prior to urine dipstick can alter results.
- Blood cultures are not routine; perform if concern for sepsis or bacteremia.

**Test Interpretation**
Depends on site of infection

---

### TREATMENT

#### GENERAL MEASURES
- Hydration
- Analgesia, if required
- Patient with indwelling catheters
  - If asymptomatic bacterial colonization, no need to treat *(Sterilization of urine is not possible, and resistant organisms may take up residence.)*
  - If symptomatic of acute infection, institute treatment.

#### MEDICATION

**First Line**
- Acute, uncomplicated cystitis
  - Treat empirically; strongly consider if nitrite positive, using local resistance patterns or based on culture and sensitivity results for 7 days.
  - For empirical therapy, a fluoroquinolone or trimethoprim-sulfamethoxazole DS usually used to treat the most likely pathogens
- Complicated, febrile, or recurrent infection
  - Prescribe a minimum of 2 weeks antibiotics based on antimicrobial sensitivities with repeat urine check after the treatment. In men with febrile UTI or pyelonephritis, prostatic involvement also must be considered. Treatment of concomitant prostatitis requires antimicrobials with good prostatic tissue and fluid penetration (fluoroquinolones).

**Second Line**
According to culture and sensitivity results and patient’s history

### ISSUES FOR REFERRAL

Further urologic evaluation and referral are warranted to rule out other disorders in male infants and men with recurrent UTI, febrile UTI, or pyelonephritis.

### ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Inability to tolerate oral medications
- Acute renal failure
Suspected sepsis

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Close follow-up until clinically well

Diet
Encourage adequate fluid intake.

PATIENT EDUCATION
For patient education materials about this topic that have been reviewed favorably, contact the National Kidney Foundation, 30 E. 33rd Street, Suite 1100, New York, NY 10016; 212-889-2210.

PROGNOSIS
Clearing of infections with appropriate antibiotic treatment

COMPLICATIONS
- Pyelonephritis
- Ascending infection
- Recurrent infection
- Prostatitis

REFERENCES

ADDITIONAL READING

SEE ALSO
- Prostate Cancer; Prostatic Hyperplasia, Benign (BPH); Prostatitis; Pyelonephritis; Urethritis
- Algorithms: Dysuria; Urethral Discharge

CODES

ICD10
- N39.0 Urinary tract infection, site not specified
- N30.90 Cystitis, unspecified without hematuria
- N30.91 Cystitis, unspecified with hematuria

CLINICAL PEARLS
- Cystitis is an infection of the lower urinary tract, usually resulting from a single gram-negative enteric bacteria.
- Risk factors/causes: age, obesity, history of UTI, BPH/outlet obstruction, incontinence, urinary tract instrumentation or catheterization, infection of the prostate/kidney, immunocompromised or diabetes, cognitive impairment, institutionalization, neurogenic bladder, uncircumcised, anal intercourse, intercourse with infected female partner
- Evaluation: urinalysis, urine culture, STI testing (e.g., gonorrhea, Chlamydia by culture/DNA probe)
- Treat empirically with fluoroquinolones or trimethoprim-sulfamethoxazole DS for 7 days.
UROLITHIASIS
Phillip Fournier, MD

BASICS

DESCRIPTION
- Stone formation within the urinary tract: Urinary crystals bind to form a nidus which grows to
  form a calculus (stone).
- Range of symptoms: asymptomatic to obstructive; febrile morbidity if result of infection

EPIDEMIOLOGY
- The worldwide epidemiology differs according to both geographic area (higher prevalence in
  hot, arid, or dry climates) and socioeconomic conditions (dietary intake and lifestyle).
  Radiolucent stones and stones secondary to infection are less influenced by environmental
  conditions.
- Vesical calculus (bladder stones) due to malnutrition during early life is frequent in Middle
  East and Asian countries.
- Incidence in industrialized countries seems to be increasing, probably due to improved
  diagnostics as well as to increasingly rich diets.
- Increased incidence in patients with surgically induced absorption issues, such as Crohn
disease and gastric bypass surgery (1)

Incidence
- In industrialized countries: 100 to 200/100,000 per year
- Predominant age: Mean age is 40 to 60 years.
- Predominant sex: male > female (~2:1) (2)

ETIOLOGY AND PATHOPHYSIOLOGY
- Supersaturation and dehydration lead to high salt content in urine which congregates.
- Stasis of urine
  - Renal malformation (e.g., horseshoe kidney, ureteropelvic junction obstruction)
  - Incomplete bladder emptying (e.g., neurogenic bladder, prostate enlargement, multiple
    sclerosis)
- Crystals may form in pure solutions (homogeneous) or on existing surfaces, such as other
  crystals or cellular debris (heterogeneous).
- Balance of promoters and inhibitors: organic (Tamm-Horsfall protein, glycosaminoglycan,
uropontin, nephrocalcin) and inorganic (citrate, pyrophosphate)
- Calcium oxalate and/or phosphate stones (80%)
  - Hypercalciuria
    o Absorptive hypercalciuria: increased jejunal calcium absorption
    o Renal leak: increased calcium excretion from renal proximal tubule
    o Resorptive hypercalciuria: mild hyperparathyroidism
  - Hypercalcemia
    o Hyperparathyroidism
    o Sarcoidosis
    o Malignancy
○ Immobilization
○ Paget disease

- Hyeroxaluria
  - Enteric hyeroxaluria
    ○ Intestinal malabsorptive state associated with irritable bowel disease, celiac sprue, or intestinal resection
    ○ Bile salt malabsorption leads to formation of calcium soaps.
  - Primary hyeroxaluria: autosomal recessive, types I and II
  - Dietary hyeroxaluria: overindulgence in oxalate-rich food

- Hyperuricosuria
  - Seen in 10% of calcium stone formers
  - Caused by increased dietary purine intake, systemic acidosis, myeloproliferative diseases, gout, chemotherapy, Lesch-Nyhan syndrome
  - Thiazides, probenecid

- Hypocitraturia
  - Caused by acidosis: renal tubular acidosis, malabsorption, thiazides, enalapril, excessive dietary protein

- Uric acid stones (10–15%): hyperuricemia causes as discussed earlier
- Struvite stones (5–10%): infected urine with urease-producing organisms (most commonly Proteus sp.)
- Cystine stones (<1%): autosomal recessive disorder of renal tubular reabsorption of cystine
- Bladder stones: seen with chronic bladder catheterization and some medications (indinavir)
- In children: usually due to malnutrition

**Genetics**
- Up to 20% of patients have a family history. However, spouses of those who form stones have higher calcium excretion rates than controls, suggesting strong dietary–environmental factors.
- Autosomal dominant: idiopathic hypercalciuria
- Autosomal recessive
  - Cystinuria, Lesch-Nyhan syndrome, hyeroxaluria types I and II
  - Ehlers-Danlos syndrome, Marfan syndrome, Wilson disease, familial renal tubular acidosis

**RISK FACTORS**
- White > African American in regions with both populations
- Family history
- Previous history of nephrolithiasis
- Diet rich in protein, refined carbohydrates, and sodium; carbonated drinks
- Occupations associated with a sedentary lifestyle or with a hot, dry workplace
- Incidence rates peak during summer secondary to dehydration.
- Obesit
- Surgically/medically induced malabsorption (Crohn disease, gastric bypass, celiac)

**GENERAL PREVENTION**
- Hydration (3)[A]
- Decrease salt and meat intake.
- Avoid oxalate-rich foods.

**Pediatric Considerations**
Rare: more common in men with low socioeconomic status

**Pregnancy Considerations**
- Pregnant women have the same incidence of renal colic as do nonpregnant women.
- Most symptomatic stones occur during the 2nd and 3rd trimesters, heralded by symptoms of flank pain/hematuria.
- Most common differential diagnosis is physiologic hydronephrosis of pregnancy. Use ultrasound to avoid irradiation. Noncontrast-enhanced CT scan also is diagnostic.
- Treatment goals
  - Control pain, avoid infection, and preserve renal function until birth or stone passage.
  - 30% require intervention, such as stent placement.

[Image]

**DIAGNOSIS**

**HISTORY**
- Pain
  - Renal colic: acute onset of severe groin and/or flank pain
  - Distal stones may present with referred pain in labia, penile meatus, or testis.
- Microscopic/gross hematuria occurs in 95% of patients.
- Nonspecific symptoms of nausea, vomiting, tachycardia, diaphoresis
- Low-grade fever without signs of infection
- Infectious origin: associated with high-grade fevers require more urgent treatment (see the following text)
- Frequency and dysuria especially occur with stones at the vesicoureteric junction (VUJ).
- Asymptomatic: nonobstructing stones within the renal calyces

**PHYSICAL EXAM**
Tender costovertebral angle with palpation/percussion and/or iliac fossa

**DIFFERENTIAL DIAGNOSIS**
- Appendicitis
- Ruptured aortic aneurysm
- Musculoskeletal strain
- Pyelonephritis (upper UTI)
- Pyonephrosis (obstructed upper UTI; emergency)
- Perinephric abscess
- Ectopic pregnancy
- Salpingitis

**DIAGNOSTIC TESTS & INTERPRETATION**
- Urinalysis for RBCs, leukocytes, nitrates, pH (acidic urine <5.5 is associated with uric acid stones; alkaline >7 with struvite stones)
- Midstream urine for microscopy, culture, and sensitivity
- Blood: urea, creatinine, electrolytes, calcium, and urate; consider CBC.
- Parathyroid hormone only if calcium is elevated
- Stone analysis if/when stone passed
Initial Tests (lab, imaging)
- Noncontrast-enhanced helical CT scan of the abdomen and pelvis has replaced IV pyelogram as the investigation of choice (4)[A].
  - Stone is found most commonly at levels of ureteric luminal narrowing: pelviureteric junction, pelvic brim, and VUJ.
  - Acute obstruction: Proximal ureter and renal pelvis are dilated to the level of obstruction, and perinephric stranding is possible on imaging.
- Renal ultrasound may be as effective with lower radiation at diagnosis as well as identifying obstruction (5)[B].
- X-ray of kidneys, ureter, and bladder to determine if stone is radiopaque or lucent
  - Calcium oxalate/phosphate stones are radiopaque.
  - Uric acid stones are radiolucent.
  - Staghorn calculi (that fill the shape of the renal calyces) are usually struvite and opaque.
  - Cystine stones are faintly opaque (ground-glass appearance).
- Ultrasound has low sensitivity and specificity but is often the first choice for pregnant women and children.

TREATMENT

GENERAL MEASURES
- 75% of patients are successfully treated conservatively and pass the stone spontaneously.
- Stones that do not pass usually require surgical intervention.
- 30–50% of patients will have recurrent stones.
- Increased fluid intake; eliminate carbonated drinks.

MEDICATION
- Medical expulsive therapy: $\alpha_1$-Antagonists (e.g., tamsulosin) (6) and calcium channel blockers (e.g., nifedipine) improve likelihood of spontaneous stone passage with a number needed to treat (NNT) of ~5.
- Category C in pregnancy
- Adequate pain control can be achieved with NSAIDs.

ISSUES FOR REFERRAL
- Urgent referral of patients with UTI/sepsis or acute renal failure/solitary kidney
- Early referral of pregnant patients, large stones (>8 mm), chronic renal failure, children
- Refer patients if no passage at 2 to 4 weeks or poorly controlled pain.

ADDITIONAL THERAPIES
- Uric acid stone dissolution therapy
  - Alkalinize urine with potassium citrate C; keep pH >6.5.
  - Allopurinol 100 to 300 mg/day PO (for those who continue to form stones despite alkalization of urine)
- Cystine stone dissolution/prevention
  - Alkalinize urine with potassium citrate; keep pH >6.5.
  - Chelating agents: captopril, $\alpha$-mercaptopropionylglycine, D-penicillamine
- Consider altering medications that increase risk of stone formation: probenecid, loop diuretics,
salicylic acid, salbutamol, indinavir, triamterene, acetazolamide.
- Vitamin D supplementation has not been proven to induce stone formation.
- Treat hypercalciuria with thiazides on an acute basis only.
- Treat hypocitraturia with potassium citrate and high-citrate juices (e.g., orange, lemon).
- Treat enteric hyperoxaluria with oral calcium/magnesium, cholestyramine, and potassium citrate.

SURGERY/OTHER PROCEDURES
- Immediate relief of obstruction is required for patients with the following conditions:
  - Sepsis
  - Renal failure (obstructed solitary kidney, bilateral obstruction)
  - Uncontrolled pain, despite adequate analgesia
- Emergency surgery for obstruction
  - Placement of a retrograde stent (i.e., endoscopic surgery, usually requires an anesthetic)
  - Radiologic placement of a percutaneous nephrostomy tube
- Elective surgery for stone treatment
  - Extracorporeal shock wave lithotripsy
  - Ureteroscopy with basket extraction/lithotripsy (laser/pneumatic)
  - Percutaneous nephrolithotomy
- Open surgery is uncommon.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Analgesia
  - Combination of NSAIDs (ketorolac 30 to 60 mg) and oral opiate
  - Parenteral opioid if vomiting or if preceding fails to control pain (morphine 5 to 10 mg IV or IM q4h)
  - Antiemetic if required or prophylactically with parenteral narcotics
- Septic patients with urosepsis or pyonephrosis may require IV antibiotics (once blood and urine cultures are taken), IV fluids, and in severe cases cardiorespiratory support in intensive care during recovery.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Patients with ureteric stones who are being treated conservatively should be followed until imaging is clear or stone is visibly passed.
  - Strain urine and send stone for composition.
  - Tamsulosin and nifedipine in selected patients to speed passage
  - Present to the hospital if pain worsens/signs of infection.
  - If pain management is suboptimal or stone does not progress or pass within 2 to 4 weeks, patient should be referred to a urologist and imaging should be repeated.
- Patients with recurrent stone formation should have follow-up with a urologist for metabolic workup: 24-hour urine for volume, pH, creatinine, calcium, cystine, phosphate, oxalate, uric acid, and magnesium.

DIET
**ALERT**
- Increased fluid intake for life cannot be overemphasized for decreasing recurrence. Encourage intake of 2 to 3 L/day; advise patient to have clear urine rather than yellow.
- Decrease or eliminate carbonated drinks.
- Patients who form calcium stones should minimize high-oxalate foods such as green leafy vegetables, rhubarb, peanuts, chocolates, and beer.
- Decrease protein and salt intake.
- Lowering calcium intake is inadvisable and may even increase urine calcium excretion.
- Increase phytate-rich foods such as natural dietary bran, legumes and beans, and whole cereal.
- Avoid excessive vitamin C and/or vitamin D.

**PROGNOSIS**
- Spontaneous stone passage depends on stone location (proximal vs. distal) and stone size (<5 mm, 90% pass; >8 mm, 10% pass).
- Stone recurrence: 50% of patients at 10 years

**REFERENCES**

**ADDITIONAL READING**
Algorithms: Dysuria; Renal Calculi; Urethral Discharge

**CODES**

ICD10
- N20.9 Urinary calculus, unspecified
- N20.0 Calculus of kidney
- N20.1 Calculus of ureter

**CLINICAL PEARLS**
- Incidence in industrialized countries seems to be increasing, probably due to improved diagnostics as well as to increasingly rich diets.
- Vesical calculosis (bladder stones) due to malnutrition during early life is frequent in Middle East and Asian countries.
- Medical expulsive therapy: \( \alpha_1 \)-Antagonists (e.g., terazosin) and calcium channel blockers (e.g., nifedipine) improve likelihood of spontaneous stone passage with NNT of \(~5\).
- Increased fluid intake for life cannot be overemphasized for decreasing recurrence. Encourage 2 to 3 L/day intake; advise patient to have clear urine rather than yellow.
- Patients who form calcium stones should minimize high-oxalate foods such as green leafy vegetables, rhubarb, peanuts, chocolates, and beer.
- Decrease protein and salt intake.
- Lowering calcium intake is inadvisable and may even increase urine calcium excretion.
URTICARIA
Todd A. Wical, DO

BASICS

DESCRIPTION
- A cutaneous lesion or lesions involving edema of the epidermis and/or dermis presenting with rapid onset and pruritus, returning to normal skin appearance within 24 hours
- Pathophysiology is primarily mast cell degranulation and subsequent histamine release.
- Angioedema may occur with urticaria, which is characterized by sudden pronounced erythematous nonpitting edema of the lower dermis and subcutis; may take up to 72 hours to remit.
- Pruritus and burning are more commonly associated with urticaria; pain more often with angioedema.
- Lesions can occur on any part of the body.
- Urticaria can be classified as acute or chronic.
  - Acute: if lesions recur within <6 weeks
  - Chronic: recurring lesions that persist for >6 weeks
- Three main causal categories of urticarial lesions
  - Immunoglobulin E (IgE) mediated
  - Non-IgE immunologically mediated
  - Nonimmunologically mediated
- Underlying etiology may be difficult to pinpoint, although in some cases possible.
- For those with chronic urticaria, 40% have concurrent angioedema.
- Etiology of urticaria is either spontaneous or induced.
- System(s) affected: integumentary
- Synonym(s): hives; wheals

EPIDEMIOLOGY

Incidence
- Equally distributed across all ages: female > male (2:1 in chronic urticaria)
- In 20% of patients, chronic urticaria lasts >10 years.

Prevalence
- 5–25% of the population
- Of people with urticaria, 40% have no angioedema, 40% have urticaria and angioedema, and 20% have angioedema with no urticaria.
- Up to 3% of the population has chronic idiopathic urticaria.

ETIOLOGY
- Mast cell degranulation with release of inflammatory reactants, which leads to vascular leakage, inflammatory cell extravasation, and dermal (angioedema) and/or epidermal (wheals/hives) edema
- Histamine, cytokines, leukotrienes, and proteases are main active substances released.
- If release of histamine and other mediators occurs in the dermis, urticaria lesions result. If release occurs deep in the dermis, then angioedema develops.
Acute spontaneous urticaria (ASU)
- Bacterial infections: strep throat, sinusitis, otitis, urinary tract
- Viral infections: rhinovirus, rotavirus, hepatitis B, mononucleosis, herpes
- Foods: peanuts, tree nuts, seafood, milk, soy, fish, wheat, and eggs; tend to be IgE-mediated; pseudoallergenic foods such as strawberries, tomatoes, preservatives, and coloring agents contain histamine.
- Drugs: IgE-mediated (e.g., penicillin and other antibiotics), direct mast cell stimulation (e.g., aspirin, NSAIDs, opiates)
- Inhalant, contact, ingestion, or occupational exposure (e.g., latex, cosmetics)
- Parasitic infection; insect bite/sting
- Transfusion reaction

Chronic spontaneous urticaria (CSU)
- Chronic subclinical allergic rhinitis, eczema, and other atopic disorders
- Chronic indolent infections: Helicobacter pylori, fungal, parasitic (Anisakis simplex, strongyloidiasis), and chronic viral infections (hepatitis)
- Collagen vascular disease (cutaneous vasculitis, serum sickness, lupus)
- Thyroid autoimmunity, especially Hashimoto
- Hormonal: pregnancy and progesterone
- Autoimmune antibodies to the IgE receptor α-chain on mast cells and to the IgE antibody
- Chronic medications (e.g., NSAIDs, hormones, ACE inhibitors). NSAID sensitivity demonstrated in almost half of adults with chronic urticaria and presents with a worsening of symptoms 4 hours after ingestion.
- Malignancy
- Physical stimuli (cold, heat, vibration, pressure) in physical urticaria

Chronic inducible urticaria (CIU)
- Dermatographism: “skin writing” or the appearance of linear wheals at the site of any type of irritation. This is the most common physical induced urticaria.
- Cold urticaria: wheals occur within minutes of rewarming after cold exposure; 95% idiopathic but can be due to infections (mononucleosis, HIV), neoplasia, or autoimmune diseases.
- Delayed pressure urticaria: urticaria occurs 0.5 to 12 hours after pressure to skin (e.g., from elastic or shoes), may be pruritic and/or painful, and may not subside for several days.
- Solar urticaria: from sunlight exposure, usually UV; onset in minutes; subsides within 2 hours
- Heat urticaria: from direct contact with warm objects or air; rare
- Vibratory urticaria/angioedema: very rare; secondary to vibrations (e.g., motorcycle)
- Cholinergic urticaria: due to brief increase of core body temperature from exercise, baths, or emotional stress. This is the second most common induced urticaria.
- Adrenergic urticaria: caused by stress; extremely rare; vasoconstricted, blanched skin around pink wheals as opposed to cholinergic’s erythematous surrounding
- Contact urticaria: wheals at sites where chemical substances contact the skin, may be either IgE-dependent (e.g., latex) or IgE-independent (e.g., stinging nettle)
- Aquagenic and solar urticaria: small wheals after contact with water of any temperature or UV light, respectively; rare

Genetics
No consistent pattern known: Chronic urticaria has increased frequency of HLA-DR4 and HLA-
D8Q MHC II alleles.

**GENERAL PREVENTION**
Avoidance of known triggers is the mainstay of prevention.

**COMMONLY ASSOCIATED CONDITIONS**
- Angioedema (common)
- Anaphylaxis (somewhat common)

**DIAGNOSIS**

**HISTORY**
Rapid onset; individual lesions resolve in <24 hours, pruritus

**ALERT**
Important to rule out underlying anaphylaxis in those patients presenting with acute onset of urticaria (1)[C], (2)[C]

**PHYSICAL EXAM**
- Single/multiple raised, polymorphic indurated plaques with central pallor and edema with an erythematous flare
- Evaluate for underlying conditions including thyroid abnormalities (nodules); bacterial, viral, or fungal infection (e.g., fever)

**DIFFERENTIAL DIAGNOSIS**
- Anaphylaxis (may present with urticaria)
- Morbilliform or fixed drug eruptions
- Erythema multiforme
- Systemic lupus erythematosus (SLE), vasculitis, and polyarteritis
- Angioedema without urticaria
- Urticaria pigmentosa/systemic mastocytosis
- Bullous pemphigoid (urticarial stage)
- Arthropod bite
- Atopic/contact dermatitis
- Viral exanthem

**DIAGNOSTIC TESTS & INTERPRETATION**
- Diagnosis is usually clinical (1)[A],(2)[A]
- In general, only if the history or physical are suggestive of a specific underlying disease should targeted laboratory studies be utilized.

**Initial Tests (lab, imaging)**
- Acute: generally not indicated
- Chronic: directed by clinical suspicion of underlying cause
  - Allergy skin tests and radioallergosorbent test (RAST) for inhaled allergens, insects, drugs, or foods
  - Infection: Consider pharyngeal culture, liver function tests (LFTs), mononucleosis test, urinalysis in appropriate setting.
Follow-Up Tests & Special Considerations
Chronic urticaria (CIU/CSU): Extensive lab testing is not indicated and has not proven to improve outcome, nor is it cost-effective. Limit lab testing according to clinical history and indication. Skin or IgE testing should be limited to specific history of provoking allergen (3).
- Complete blood count, Erythrocyte sedimentation rate (ESR), and C-reactive protein are recommended by most guidelines.
- Thyroid function tests, LFTs, and urinalysis are recommended by several guidelines.
- Consider allergy skin tests and RAST for inhaled allergens, insects, drugs, or foods; total IgE level
- Autoimmune: ESR, ANA, RF, complement (e.g., CH50, C3, C4), cryoglobulins in urticarial vasculitis
- Tests for H. pylori (e.g., antibodies) in dyspeptic patients. Consider stool for ova and parasites in at-risk individuals.
- Autologous serum skin testing: injection of serum under skin to test for presence of IgE receptor–activating antibodies
- Consider malignancy workup, including serum protein electrophoresis and immunofixation in the proper setting.

Diagnostic Procedures/Other
- Food and drug reactions: elimination of (or challenges with) suspected agents
- Physical and special forms of urticaria challenge tests:
  - Dermatographism: Stroke skin lightly with rounded object and observe for surrounding urticaria.
  - Cold urticaria: ice cube test—place ice cube on skin for 5 minutes; observe for 10 to 15 minutes.
  - Cholinergic: Exercise to the point of sweating; partial immersion in 42°C bath for 10 minutes
  - Solar: Expose to different wavelengths of light.
  - Delayed pressure: Apply 5-lb. sandbag to back for 20 minutes; observe 6 hours later.
  - Aquagenic: Apply water at various temperatures.
  - Vibratory: Apply vibration 4 to 5 minutes with a lab mixing device; observe.
- Skin biopsy with lesions lasting >24 hours or if concern for underlying vasculitis (1)[A],(2)[A]

TREATMENT

GENERAL MEASURES
The mainstay of therapy for urticaria is the avoidance of identified triggers.

MEDICATION
First Line
2nd-generation antihistamine (H1) blockers are the first-line treatment of any urticaria in which avoidance of stimulus is impossible or not feasible (1)[A],(2)[A]:
- Fexofenadine (Allegra): 180 mg/day
- Loratadine (Claritin): 10 mg/day, increasing to 30 mg/day if needed; only medication studied for safe use in pregnancy
Desloratadine (Clarinex): 5 mg/day (4)[A]
Cetirizine (Zyrtec): 10 mg/day, increasing to 30 mg per day if needed
Levocetirizine (Xyzal): 5 mg/day; requires weight-based dosing in children (4)[A]
Rupatadine: novel H₁ antagonist with antiplatelet-activating factor activity

**Second Line**
Doubling the typical 2nd-generation H₁ blocker dosages should be attempted before adding 1st-generation H₁ or H₂ blockers (1)[A], (2)[A], (4)[A].

- H₂-specific antihistamines (beneficial as adjuvants): cimetidine, ranitidine, nizatidine, famotidine
- 1st-generation antihistamines (H₁; for patients with sleep disturbed by itching):
  - Older children and adults: hydroxyzine or diphenhydramine 25 to 50 mg q6h
  - Children <6 years of age: diphenhydramine 12.5 mg q6–8h (5 mg/kg/day) or hydroxyzine 10 mg/5 mL (2 mg/kg/day) divided q6–8h

**Geriatric Considerations**
1st-generation H₁ blockers may cause excessive drowsiness as well as dry mouth and eyes.

**ISSUES FOR REFERRAL**
Referral to an allergist, immunologist, or dermatologist for recalcitrant cases, especially if lesions consistently remain present for >24 hours

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Educating patient on use of EpiPen as pathophysiology is similar to anaphylaxis; if the airway is threatened, immediate consultation to evaluate for laryngeal edema and need for definitive airway management

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
After initial diagnosis, follow-up is recommended within 6 weeks as nearly 1/3 of acute patient go on to have persistent urticaria.

**Patient Monitoring**
- Use the urticaria activity score (UAS7) for assessing CSU.
- Recently developed urticaria control test (UCT)
  - The tool to assess disease control in patients with chronic urticaria (spontaneous and inducible) (5)[A]

**PROGNOSIS**
- Resolution of acute symptoms: 70% <72 hours
- Chronic urticaria: 35% symptom-free in a year; another 30% will see symptom reduction

**REFERENCES**

ADDITIONAL READING

CODES

ICD10
- L50.9 Urticaria, unspecified
- L50.1 Idiopathic urticaria
- L50.8 Other urticaria

CLINICAL PEARLS

- Urticaria occurs rapidly and individual lesions resolve within 24 hours, although multiple crops of lesions can occur in stages.
- Mainstay of therapy is to avoid identified triggers.
- Antihistamines are the best studied and most efficacious therapy but may require higher-than-normal doses for efficacy.
- If individual lesions last >24 hours, patient should be evaluated for urticarial vasculitis and other more serious diagnoses.
UTERINE AND PELVIC ORGAN PROLAPSE
Deepali Maheshwari, DO, MPH • Michael Flynn, MD, MHS

BASICS

DESCRIPTION
- Symptomatic descent of one or more of (1,2)
  - The anterior vaginal wall (bladder or cystocele)
  - The posterior vaginal wall (rectum or rectocele)
  - The uterus and cervix
  - The vaginal apex (vault or cuff scar after hysterectomy)
- Prolapses above or to the level of the hymen are generally not symptomatic (2).

Associated symptoms (2)
- Feeling of vaginal or pelvic pressure
- Heaviness
- Bulging
- Bowel or bladder symptoms

Cost associated with treatment is >$1 billion annually (~200,000 surgeries per year) (2).

EPIDEMIOLOGY

Incidence
- The incidence of pelvic organ prolapse (POP) ranges from 1.5 to 1.8 per 1,000 woman years and peaks in women aged 60 to 69 years (3).
- In the United States, there are approximately 300,000 surgeries for POP each year (3), and a woman’s lifetime risk of undergoing surgery for pelvic floor prolapse ranges from 6% to 18% (3).

Prevalence
- A national survey of 7,924 women (>20 years of age) found a prevalence of 25% for one or more pelvic floor disorders (including urinary incontinence, fecal incontinence, and POP). Prevalence of POP was 3–6% (4).
- POP is common but not always symptomatic. It does not always progress. It is estimated that 50% of women will develop prolapse, but only 10–20% of those will seek care for their condition (3).

ETIOLOGY AND PATHOPHYSIOLOGY
- Pelvic organs are supported by attachments between pelvic floor muscles, connective tissue, and the bony pelvis. Defects in this support can lead to prolapse in one or multiple compartments (5).
- Symptomatic women typically have defects in more than one compartment as well as damage to the levator ani and its attachments to the pelvis (5).
- Gradual process that begins long before symptoms develop

RISK FACTORS
- Vaginal childbirth: Each additional vaginal birth increases risk (2,4).
- Age
Family history (2)
Race: White and Hispanic women may be at higher risk than black or Asian women (1,2).
Obesity BMI >30 kg/m² (2,4)
Chronic straining (constipation, chronic cough from pulmonary disease, repeated heavy lifting) (2)
History of hysterectomy (2,4)

GENERAL PREVENTION
There is some evidence that pelvic floor muscle training ("Kegel exercises") may decrease the risk of symptomatic POP (5)[B]. Weight loss and proper management of conditions that cause increase in intra-abdominal pressure such as constipation may help prevent prolapse (5)[C]. Elective caesarean delivery has not been shown to prevent prolapse.

COMMONLY ASSOCIATED CONDITIONS
- Constipation
- Fecal incontinence
- Urinary incontinence or retention
- Other urinary symptoms
  - Urgency
  - Frequency

DIAGNOSIS
Less than half of women discuss symptoms with PCP. Only 10–12% seek medical attention. Barriers include embarrassment, social stigma, ability to cope, belief that POP is part of the aging process, belief that treatment options are limited, and fear of surgery.

HISTORY
- Common symptoms include the following:
  - Feeling a bulge in vagina
  - Something “falling out” of vagina
  - Pelvic pressure with activity or prolonged standing
  - Difficulty with voiding or defecation
  - Splinting the bulge to evacuate
  - Urinary or fecal urgency
  - Urinary frequency
  - Urinary or fecal incontinence
  - Constipation
- Document the presence, duration, and severity of coexisting urinary or bowel symptom.
- Assess impact on sexual function and quality of life.
- Assess past medical and surgical history.
  - Gravity and parity/obstetric history
  - Chronic constipation
  - Pulmonary disease
  - Prior pelvic procedures

PHYSICAL EXAM
Abdominal examination to document any distention or masses

Complete pelvic and rectal examination. Have patient cough or strain, particularly in an upright (standing) position while examining the distal vagina.

The standard to measure prolapse is the validated Pelvic Organ Prolapse Quantification (POP-Q) scale.
  – Describes prolapse of each compartment in relationship to the vaginal hymen
  – Patient is supine with the head of the bed at 45 degrees, performing Valsalva.
    o Stage 1: prolapse in which the distal point is superior or equal to 1 cm above hymen
    o Stage 2: prolapse in which the distal point is between 1 cm above and 1 cm below hymen
    o Stage 3: prolapse in which the distal point is superior or equal to 1 cm below the hymen, but some vaginal mucosa is not everted
    o Stage 4: complete vaginal vault eversion (“procidentia”); entire vaginal mucosa everted

A split speculum should be used to observe apical, anterior, and posterior compartments successively.

Patient can be evaluated in supine position. If prolapse is not well demonstrated, patient can stand and Valsalva to assess maximum descent.

DIFFERENTIAL DIAGNOSIS

- Rectal prolapse
- Hemorrhoids
- Bartholin cyst
- Vaginal cyst
- Urethral diverticulum
- Cervical elongation

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Urinalysis if symptomatic POP (1)
- Postvoid residual (1)

Follow-Up Tests & Special Considerations
- Consider urodynamics if results would alter treatment plan.
- Selective use of upper urinary tract imaging if observation is planned or if evidence of obstruction (e.g., abnormal postvoid residual) (1)
- If fecal incontinence or significant change in bowel habits, selective use of lower GI tract imaging or endoscopy (1)
- Consider defecography if severity of symptoms is out of proportion with the extent of prolapse.

TREATMENT

GENERAL MEASURES
- Treatment is generally guided by degree of bother for the patient. It is important to document the patient’s desire, goals, and expectations.
- Treatment should consider type and severity of symptoms, patient’s age, other comorbid
conditions, sexual function, infertility, and risk of recurrence.

- Treatment for asymptomatic patients:
  - Stage 1 or 2: clinical observation
  - Stage 3 or 4: regular follow-up and evaluation (every 3 to 6 months) (2)
- Expectant management is an acceptable option for patients without evidence of urinary or bowel obstruction.
- Treatment is indicated when there is urinary/bowel obstruction or hydronephrosis regardless of the degree of prolapse.
- A vaginal pessary should be considered in all women presenting with symptomatic prolapse.
  - There are >13 types of pessaries.
  - The most commonly used pessaries are the ring pessary and Gellhorn.
  - Most women can be successfully fitted with a pessary.
  - Satisfaction rate for patients using pessaries is very high (5).
- Minor complications such as vaginal discharge and odor can often be treated with vaginal estrogen.
- Vaginal erosion can be treated by removal of pessary and optional vaginal estrogen supplementation.
- Complications such as erosions, abrasions, ulcerations, vaginal bleeding, and fistulas may be seen with neglected pessaries.

**MEDICATION**

There are no data to support the use of vaginal estrogen or other medications for the prevention or treatment of POP.

**ISSUES FOR REFERRAL**

Referral when pessary or surgery is necessary

**ADDITIONAL THERAPIES**

Pelvic floor muscle training: may reduce the symptoms of POP. Pelvic floor muscle training does not affect the degree of prolapse, only the symptoms (5).

**SURGERY/OTHER PROCEDURES**

- Reconstructive procedures are performed with the goal of restoration of vaginal anatomy and resolution of symptoms.
- There are a variety of surgeries for repair of the anterior, apical, and posterior compartments. Surgical approaches include vaginal, abdominal, laparoscopic (straight stick and robot assisted).
- Reconstructive surgery using native tissue is associated with an elevated rate of failure (1 in 3 lifetime risk of repeat surgery). Procedures, using surgical mesh and graft material, have higher success rates.
- Surgical repair should focus on repairing all affected compartments in a single procedure.
- Coexisting stress incontinence should be addressed at the same time as the prolapse repair.
- For apical repairs:
  - Sacral colpopexy uses surgical mesh and has higher success rates and overall durability. It can be performed abdominally, laparoscopically, or robotically. The risk of recurrent prolapse is considered lower with sacral colpopexy than vaginal approaches; there may be an elevated risk of complications (6).
  - Concomitant hysterectomy is generally performed with prolapse repair. The risk of mesh
extrusions appears to be decreased by retaining the cervix.
- Uterine preservation via hysteropexy is also an option and may be offered by some surgeons. The risks and benefits of uterine preservation in prolapse repair remain unclear.

**ONGOING CARE**

**PATIENT EDUCATION**
- Patients should have POP explained to them with diagrams and descriptions of their anatomy.
- Important to emphasize that surgery is geared toward improving quality of life.
- Patients should be educated about pessary complications and possible symptoms of POP if they are still asymptomatic.
- Using insoluble fibers may help patients with bowel complaints such as constipation.

**COMPLICATIONS**
- Recurrence rates are variable and quoted between 3.4% and 29.2% (3).
- There is a risk of dyspareunia and pelvic pain after any surgical repair. Those repairs using mesh may also be complicated by mesh erosion (6).
- Risk of complications with pessary includes vaginal erosion and fistula in patients that are lost to follow-up.
- Severe prolapse can lead to urinary retention and defecatory dysfunction that may go unrecognized in the elderly.

**REFERENCES**

**CODES**

**ICD10**
- N81.9 Female genital prolapse, unspecified
- N81.10 Cystocele, unspecified
- N99.3 Prolapse of vaginal vault after hysterectomy
CLINICAL PEARLS

- Many women do not discuss POP with their doctor—ask routinely.
- Vaginal pessary should be considered in all patients with symptomatic prolapse.
- Treatment should be guided by degree of bother and impact on patient’s quality of life.
UTERINE MYOMAS
Christina N. Kufel, DO, MS • Michael P. Hopkins, MD, MEd

BASICS

DESCRIPTION
- Uterine leiomyomas are well-circumscribed, pseudoencapsulated, benign monoclonal tumors composed mainly of smooth muscle with varying amounts of fibrous connective tissue (1).
- Three major subtypes
  - Subserous: common; external; may become pedunculated
  - Intramural: common; within myometrium; may cause marked uterine enlargement
  - Submucous: ~5% of all cases; internal, evoking abnormal uterine bleeding and infection; occasionally protruding from cervix
- Rare locations: broad, round, and uterosacral ligaments
- System affected: reproductive
- Synonym(s): fibroids; myoma; fibromyoma; myofibroma; fibroleiomyoma

EPIDEMIOLOGY

Incidence
- Cumulative incidence up to 80%
  - 60% in African American women by age 35 years; 80% by age 50 years
  - 40% in Caucasian women by age 35 years; 70% by age 50 years (1,2,3)
- Incidence increases with each decade during reproductive years.
- Rarely seen in premenarchal females
- Predominant sex: females only

ETIOLOGY AND PATHOPHYSIOLOGY

- Enlargement of benign smooth muscle tumors that may lead to symptoms affecting the reproductive, GI, or genitourinary system
- Complex multifactorial process involving transition from normal myocyte to abnormal cells and then to visibly evident tumor (monoclonal expansion)
  - Hormones (1): Increases in estrogen and progesterone are correlated with myoma formation (i.e., rarely seen before menarche). Estrogen receptors in myomas bind more estradiol than normal myometrium.
  - Growth factors (1)
    o Increased smooth muscle proliferation (transforming growth factor β [TGF-β], basic fibroblast growth factor [bFGF])
    o Increase DNA synthesis (epidermal growth factor [EGF], platelet-derived growth factor [PDGF], activin, myostatin)
    o Stimulate synthesis of extracellular matrix (TGF-β)
    o Promote mitogenesis (TGF-β, EGF, insulin-like growth factor [IGF], prolactin)
    o Promote angiogenesis (bFGF, vascular endothelial growth factor [VEGF])
  - Vasoconstrictive hypoxia (1): proposed, but not confirmed, mechanism of myometrial injury during menstruation

Genetics
A variety of somatic chromosomal rearrangements have been described in 40% of uterine myomas.
- Mutations in the gene encoding mediator complex subunit 12 (MED12) on the X chromosome were found in 70% of myomas in one study (2).
- Higher levels of aromatase and therefore estrogen have been found in myomas in African American women (2).

RISK FACTORS
- African American heritage
  - 2.9 times greater risk than Caucasian women; occur at a younger age, are more numerous, larger, and more symptomatic (1,3)
- Early menarche (<10 years)
- Oral contraceptive use before 16 years old (3)
- Nulliparous
- Hypertension
- Familial predisposition
  - 2.5 times more likely in women with a first-degree relative with myomas (1)
- Obesity
  - Risk increases by 21% with each 10 kg of weight gain (1).
- Alcohol
  - Risk decreased by parity, progesterone-only contraceptives, diet (fruits, veggies, low fat dairy) (3)

COMMONLY ASSOCIATED CONDITIONS
Endometrial and breast cancer also associated with high, unopposed estrogen stimulation

DIAGNOSIS

HISTORY
- Usually asymptomatic; 30% present with abnormal symptoms—usually enlarged uterus or heavy bleeding (3).
- Symptoms include the following:
  - Abnormal uterine bleeding: usually heavy/prolonged menses
  - Pain: infrequent; usually associated with torsion of pedunculated myoma, degeneration, or cervical dilation by submucous myoma near cervical os
  - Pressure on bladder: suprapubic discomfort, urinary frequency/obstruction
  - Pressure on rectosigmoid: may cause low back pain, constipation
  - Infertility: rare, estimated 1–2.5%; usually from submucous myoma distorting the uterine cavity or interference with implantation

ALERT
Rapid growth, particularly in perimenopausal/postmenopausal patients; may indicate sarcoma; extremely rare, 0.1–0.3% of cases

PHYSICAL EXAM
- Usually incidental finding on abdominal and pelvic exam
- Firm, smooth nodules/masses arising from uterus
Masses are mobile without tenderness.

DIFFERENTIAL DIAGNOSIS
- Intrauterine pregnancy
- Cancer, including ovarian, uterine, or leiomyosarcoma
- Cecal/sigmoid tumor
- Appendiceal abscess
- Diverticulitis
- Pelvic kidney
- Urachal cyst

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Pregnancy test
- Hemoglobin
- Pelvic ultrasound: standard confirmatory test; shows characteristic hypoechoic appearance
  - (3,4)
- Saline infusion hysterosonography: helps to distinguish submucosal myomas
- Hysterosalpingogram: evaluates the contour of the endometrial cavity (4)
- CT scan or MRI: provides info on degeneration and special relationships
- May help to differentiate complex cases or used when uterine artery embolization is planned (4)[B]

Follow-Up Tests & Special Considerations
Consider cancer antigen 125 (CA-125): may be slightly elevated in some cases of uterine myoma but generally more useful in differentiating myomas from various gynecologic adenocarcinomas
- IV pyelogram: if suspect ureteral distortion (4)
- Barium enema

Diagnostic Procedures/Other
- Fractional dilation and curettage: aids in ruling out cervical/uterine carcinomas when clinically suspicious
- Hysteroscopy: helps to diagnose submucosal/intracavitary myomas
- Laparoscopy: useful in complex cases and to rule out other pelvic diseases/disorders

Test Interpretation
- Myomas are usually multiple and vary in size and location; have been reported up to 100 lb
- Gross pathology: firm tumors with characteristic whorl-like trabeculated appearance; a thin pseudocapsular layer is present.
- Microscopic: bundles of smooth muscle mixed with varying amounts of connective tissue elements running in different directions
- Cellular variant has a preponderance of muscle cells. Mitoses are rare.
- May undergo various types of degeneration
  - Hyaline degeneration: very common
  - Calcification: late result of circulatory impairment to myomas
  - Infection and suppuration: most common with submucosal myomas
  - Necrosis: most common with pedunculated myomas secondary to torsion
**TREATMENT**

- Treatment must be individualized and based on symptoms, fertility desires, and time until menopause.
- Medical therapy may be of benefit.
- Patients with minimal symptoms may be treated with iron preparations and analgesics.
- Conservative management of asymptomatic myomas
  - Pelvic exams and ultrasounds at ≥3-month intervals if size remains stable
  - Substantial regression usually occurs after menopause.
- Surgical options should be considered if symptomatic or worrisome myomas are unresponsive to conservative/medical management.

**GENERAL MEASURES**

Patients not desiring pharmacologic therapy or surgery may consider the following:

- Uterine artery embolization: averages 50% shrinkage of myomas (5)[A]; painful and may cause ovarian failure (1–2%), amenorrhea, postembolization syndrome, or other complications; shorter hospital stay and quicker recovery but no difference in satisfaction compared with hysterectomy (3)[B]; high reintervention rate (15–32% by 2 years) compared to hysterectomy/myomectomy (7% by 2 years) (5)
- MR-guided focused ultrasound (MRgFUS): noninvasive, ultrasound transducer passes through abdominal wall and causes coagulative necrosis of fibroid; up to 98% reduction in myoma volume and symptoms. Not appropriate for some types of myomas. Efficacy may be comparable with other hysterectomy-sparing procedures. Fertility has been shown to be preserved (3)[A], although risks and outcomes data are limited (3).

**MEDICATION**

- Progestins may reduce overall uterine size (4)[B].
  - Norethindrone 10 mg/day
  - Medroxyprogesterone 200 mg IM monthly
  - Levonorgestrel intrauterine device
- Combination oral contraceptives: may help prevent development of new fibroids and control bleeding
  - Contraindications: history of thromboembolic events
- Gonadotropin-releasing hormone agonists
  - Nafarelin (nasal spray), goserelin acetate, and leuprolide
    - Induces abrupt artificial menopause; may reduce myoma symptoms dramatically; induces atrophy of myomas by up to 40% in 2 to 3 months (4)[B]
    - May be valuable as preoperative adjunct to myomectomy/hysterectomy by allowing recovery of anemia, donation of autologous blood, and possibly converting abdominal to vaginal hysterectomy (3,4,6)[B]
    - Not recommended for use >6 months because of osteoporosis risk
    - Following discontinuation, myomas return within 60 days to pretherapy size.
- Antiprogestones
  - Mifepristone
    - Shown to have similar reduction in myoma size as gonadotropin-releasing hormone agonists
    - Decreases heavy bleeding and increases quality of life (7)[A]
– Selective progesterone receptor modulator (SPRM)
  – Ulipristal acetate: may be as effective as gonadotropin-releasing hormones with fewer side effects (3)[B]

**ISSUES FOR REFERRAL**
- Medical therapy may be initiated by a primary care physician/gynecologist after adequate pelvic examination.
- Surgical considerations may be pursued with gynecologic consultation.
- Uterine embolization may be discussed with an interventional radiologist.

**SURGERY/OTHER PROCEDURES**
- Surgical management is indicated in the following situations (4)[B]:
  - Excessive uterine size or excessive rate of growth (except during pregnancy)
  - Submucosal myomas when associated with hypermenorrhea
  - Pedunculated myomas that are painful or undergo torsion, necrosis, and hemorrhage
  - If a myoma causes symptoms from pressure on bladder/rectum
  - If differentiation from ovarian mass is not possible
  - If associated pelvic disease is present (endometriosis, pelvic inflammatory disease)
  - If infertility/habitual abortion is likely due to the anatomic location of the myoma
- Surgical procedures
  - Preliminary pelvic examination, Pap smear, and endometrial biopsy should be performed to rule out malignant/premalignant conditions.
  - Hysterectomy: may be performed vaginally, laparoscopically, robotically, or by laparotomy
    - Effective in relieving symptoms and improving quality of life (3)[B]
    - FDA discourages the use of laparoscopic power morcellation during hysterectomy or myomectomy for uterine fibroids given the risk of spreading an occult malignancy and all patients should be counseled preoperatively of risk (3).
  - Abdominal, laparoscopic, robotic, or hysteroscopic myomectomy may be performed in younger women who want to maintain fertility (4,8)[B].
    - Hysteroscopic/laparoscopic cautery/laser myoma resection can be performed in selected patients.
    - Endometrial ablation: for small submucosal myomas

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Usually outpatient
- Inpatient for some surgical procedures

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Pelvic examination and ultrasound: every 2 to 3 months for newly diagnosed symptomatic/excessively large myomas
- Hemoglobin and hematocrit: if uterine bleeding is excessive
- Once uterine size and symptoms stabilize, monitor every 6 to 12 months although no high-
quality evidence exists (3).

**DIET**
No restrictions

**PATIENT EDUCATION**
- American Congress of Obstetricians and Gynecologists: [http://www.acog.org](http://www.acog.org)

**PROGNOSIS**
- Resection of submucosal fibroids has been associated with increased fertility.
- At least 10% of myomas recur after myomectomy; however, only 25% require further treatment (3)[B].

**COMPLICATIONS**
- May mask other gynecologic malignancies (e.g., uterine sarcoma, ovarian cancer)
- Degenerating fibroids may cause pain and bleeding.
- May rarely prolapse through the cervix

**Pregnancy Considerations**
- Rapid growth of fibroids is common.
- Pregnant women may need additional fetal testing if placenta is located over or near fibroid.
- Complications during pregnancy: abortion, premature labor, 2nd-trimester rapid growth leading to degeneration/pain, 3rd-trimester fetal malpresentation, and dystocia during labor and delivery
- Cesarean section is recommended if the endometrial cavity was entered during myomectomy due to increased risk of uterine rupture.

**Geriatric Considerations**
Postmenopausal patients with newly diagnosed uterine myoma/enlarging uterine myomas have a high suspicion of uterine sarcoma/other gynecologic malignancy.

**REFERENCES**

ADDITIONAL READING

CODES

ICD10
- D25.9 Leiomyoma of uterus, unspecified
- D25.2 Subserosal leiomyoma of uterus
- D25.1 Intramural leiomyoma of uterus

CLINICAL PEARLS
- Uterine myomas are benign smooth muscle tumors composed mainly of fibrous connective tissue.
- Usually incidental finding on pelvic exam or ultrasound but may cause pelvic pain and pressure, abnormal uterine bleeding, and/or infertility
- Management ranges from conservative to medical to surgical.
UVEITIS
Mikayla L. Spangler, PharmD ● Laura K. Klug, PharmD ● Michael Allen Greene, MD

**BASICS**

**DESCRIPTION**
- A nonspecific term used to describe any intraocular inflammatory disorder
- Symptoms vary depending on depth of involvement and associated conditions.
- The uvea is the middle layer of the eye between the sclera and retina. The anterior part of the uvea includes the iris and ciliary body. The posterior part of the uvea is the choroid.
  - Anterior uveitis: refers to ocular inflammation limited to the iris (iritis) alone or iris and ciliary body (iridocyclitis)
  - Intermediate uveitis: refers to inflammation of the structures just posterior to the lens (pars planitis or peripheral uveitis)
  - Posterior uveitis: refers to inflammation of the choroid (choroiditis), retina (retinitis), or vitreous near the optic nerve and macula
- System(s) affected: nervous
- Synonym(s): iritis; iridocyclitis; choroiditis; retinochoroiditis; chorioretinitis; anterior uveitis; posterior uveitis; pars planitis; panuveitis. Synonyms are anatomic descriptions of the focus of the uveal inflammation.

**Geriatric Considerations**
The inflammatory response to systemic disease may be suppressed.

**Pediatric Considerations**
- Infection should be the primary consideration.
- Allergies and psychological factors (depression, stress) may serve as a trigger.
- Trauma is also a common cause in this population.

**Pregnancy Considerations**
May be of importance in the selection of medications

**EPIDEMIOLOGY**
- Predominant age: all ages
- Predominant sex: male = female, except for human leukocyte antigen B27 (HLA-B27) anterior uveitis: male > female, autoimmune etiology: female > male

**Incidence**
- Overall incidence is 17 to 52 cases/100,000 per year in the developed world.
- Anterior uveitis is the most common.

**Prevalence**
- Overall prevalence is 38 to 714 cases/100,000 annual incidence.
- Anterior uveitis is the most common with iritis being 4 times more prevalent than posterior uveitis.
ETIOLOGY AND PATHOPHYSIOLOGY
- Infectious: may result from viral, bacterial, parasitic, or fungal etiologies
- Suspected immune mediated: possible autoimmune or immune complex–mediated mechanism postulated in association with systemic (especially rheumatologic) disorders
  - Autoimmune uveitis (AIU) patients should be referred to an ophthalmologist for local treatment.
- Isolated eye disease
- Idiopathic (~25%)
- Some medications may cause uveitis. The most causative medications include rifabutin, bisphosphonates, sulfonamides, metipranolol, topical corticosteroids, brimonidine, prostaglandin analogs, anti–vascular endothelial growth factor (VEGF) agents, bacillus Calmette-Guérin (BCG) vaccination, and systemic and intraocular cidofovir.
- Masquerade syndromes: diseases such as malignancies that may be mistaken for primary inflammation of the eye

Genetics
- No specific pattern for uveitis in general (1)
- Iritis: 50–70% are HLA-B27 positive.
- Predisposing gene for posterior uveitis associated with Behçet disease may include HLA-B51.

RISK FACTORS
- No specific risk factors
- Higher incidence is seen with specific associated conditions.

COMMONLY ASSOCIATED CONDITIONS
- Viral infections: herpes simplex, herpes zoster, HIV, cytomegalovirus, congenital Zika virus
- Bacterial infections: brucellosis, leprosy, leptospirosis, Lyme disease, propionibacterium infection, syphilis, tuberculosis (TB), Whipple disease
- Parasitic infections: acanthamebiasis, cysticercosis, onchocerciasis, toxocariasis, toxoplasmosis
- Fungal infections: aspergillosis, blastomycosis, candidiasis, coccidioidomycosis, cryptococcosis, histoplasmosis, sporotrichosis
- Suspected immune mediated: ankylosing spondylitis, Behçet disease, Crohn disease, drug or hypersensitivity reaction, interstitial nephritis, juvenile rheumatoid arthritis, Kawasaki disease, multiple sclerosis, psoriatic arthritis, Reiter syndrome, relapsing polychondritis, sarcoidosis, Sjögren syndrome, systemic lupus erythematosus, ulcerative colitis, vasculitis, vitiligo, Vogt-Koyanagi (Harada) syndrome
- Isolated eye disease: acute multifocal placoid pigmented epitheliopathy, acute retinal necrosis, birdshot choroidopathy, Fuchs heterochromic cyclitis, glaucomatocyclitic crisis, lens–induced uveitis, multifocal choroiditis, pars planitis, serpiginous choroiditis, sympathetic ophthalmia, trauma
- Masquerade syndromes: leukemia, lymphoma, retinitis pigmentosa, retinoblastoma

DIAGNOSIS

HISTORY
- Decreased visual acuity
- Pain, photophobia, blurring of vision (2)[C]
  - Usually acute
- Anterior uveitis (~80% of patients with uveitis) (2)[C]
  - Generally acute in onset
  - Deep eye pain
  - Photophobia (consensual)
- Intermediate and posterior uveitis (3)
  - Unresolving floaters
  - Generally insidious in onset
  - More commonly bilateral

**PHYSICAL EXAM**
Slit-lamp exam and indirect ophthalmoscopy are necessary for precise diagnosis (2)[C].
- Anterior uveitis (~80% of patients with uveitis)
  - Conjunctival vessel dilation
  - Perilimbal (circumcorneal) dilation of episcleral and scleral vessels (ciliary flush)
  - Small pupillary size of affected eye
  - Hypopyon or hyphema (WBCs or RBCs pooled in the anterior chamber)
  - Frequently unilateral (95% of HLA-B27–associated cases); if first occurrence and otherwise asymptomatic, no further diagnostic testing is needed (2)[C].
  - Bilateral involvement and systemic symptoms (fever, fatigue, abdominal pain) may be associated with interstitial nephritis (2)[C].
  - Systemic disease is most likely to be associated with anterior uveitis (in one study, 53% of patients were found to have systemic disease) (2)[C].
- Intermediate and posterior uveitis
  - More commonly bilateral
  - Posterior inflammation will generally cause minimal pain or redness unless associated with an iritis.

**DIFFERENTIAL DIAGNOSIS**
- Acute angle-closure glaucoma
- Conjunctivitis
- Episcleritis
- Keratitis
- Scleritis

**DIAGNOSTIC TESTS & INTERPRETATION**
No specific test for the diagnosis of uveitis. Tests for etiologic factors or associated conditions should be based on history and physical exam (2)[C],(4).

**Initial Tests (lab, imaging)**
- Complete blood count, blood urea nitrogen, creatinine (interstitial nephritis) (2)[C]
- HLA-B27 typing (ankylosing spondylitis, Reiter syndrome) (2)[C]
- Antinuclear antibody, ESR (systemic lupus erythematosus, Sjögren syndrome) (2)[C]
- Venereal disease research laboratory (VDRL) test, fluorescent titer antibody (syphilis) (2)[C]
- Fluorescent treponemal antibody absorption (FTA-ABS) or microhemagglutination assay for antibodies to Treponema pallidum (MHA-TP) (2)[C]
- Purified protein derivative (PPD) tuberculin skin test (TB) (2)[C]
- Lyme serology (Lyme disease) (2)[C]
- Disorders that may alter lab results: immunodeficiency
- Chest x-ray (sarcoidosis, histoplasmosis, tuberculosis, lymphoma) (2)[C]
- Sacroiliac radiograph (ankylosing spondylitis) (2)[C]

**Diagnostic Procedures/Other**

Slit-lamp exam (2)[C]

**Test Interpretation**

- Keratic precipitates
- Inflammatory cells in anterior chamber or vitreous
- Synechiae (fibrous tissue scarring between iris and lens)
- Macular edema
- Perivasculitis of retinal vessels

**TREATMENT**

**GENERAL MEASURES**

- Outpatient care with urgent ophthalmologic consultation
- Medical therapy is best initiated following full ophthalmologic evaluation.
- Treatment of underlying cause, if identified
- Anti-inflammatory therapy

**MEDICATION**

**First Line**

- The treatment depends on the etiology, location, and severity of the inflammation.
- Prednisolone acetate 1% ophthalmic suspension: 1–2 drops to the affected eye 2–4 times per day, during first 24–48 hours, dosing frequency may be increased or Dexamethasone 0.1% ophthalmic suspension: 1–2 drops to affected eye 4–6 times per day, may use hourly in severe disease
  - Taper prior to discontinuation
  - Contraindications
    - Hypersensitivity to the medication or component of the preparation
    - Topical corticosteroid therapy is contraindicated in uveitis secondary to infectious etiologies, unless used in conjunction with appropriate anti-infectious agents.
  - Precautions
    - Topical corticosteroids may increase intraocular pressure, increase susceptibility to infections, impair corneal or scleral wound healing, or cause corneal epithelial toxicity or crystalline keratopathy. Prolonged use may cause cataract formation and exacerbate existing herpetic keratitis, which may masquerade as iritis.
    - Significant possible interactions
- Systemic corticosteroids are useful for maintenance therapy for patients with noninfectious uveitis or for severe ocular inflammation. These should always be used with other immunosuppressive medications for steroid-sparing effects; prednisone 5 to 10 mg daily (5,6)[B]
Cycloplegic agents may be used to dilate the eye and relieve pain. Agents include scopolamine hydrobromide 0.25% (Isopto Hyoscine) or atropine 1% 1 to 2 drops up to QID, or homatropine hydrobromide (Isopto) 2% or 5% 1 to 2 drops BID or as often as q3h if necessary (2)[C].
  
  - Contraindications
  - Cycloplegia is contraindicated in patients known to have, or be predisposed to, glaucoma.
  - Precautions
  - Use extreme caution in infants, young children, and elderly because of increased susceptibility to systemic effects.

Second Line

- Anti-inflammatory: prednisolone sodium phosphate 1%, dexamethasone sodium phosphate 0.1%, rimexolone 1% (Vexol), and loteprednol etabonate 0.5% (Lotemax), difluprednate (Durezol) 0.05% (2,6)[C]

- Rimexolone 1% (Vexol) may be equally effective as prednisolone acetate 1% for short-term treatment of anterior uveitis (2)[C].

- Loteprednol etabonate (Lotemax) may not be as effective as prednisolone acetate 1% but may be less likely to increase intraocular pressure in cases of acute anterior uveitis.

- Periocular corticosteroids may be injected with triamcinolone acetonide being most commonly used; 40 mg/1 mL (7)[C].

- Intravitreous corticosteroid deposits may also be used for long-term maintenance; fluocinolone acetonide (Retisert) 590 μg released >30 months, dexamethasone (Ozurdex) 0.7 mg released slowly >3 to 6 months (6,7)[B].

  Retisert has caused all patients to develop cataracts and significant increases in intraocular pressure in about 2/3 of patients, whereas Ozurdex had only 1/4 of patients require medication for increased intraocular pressure and 15% develop cataracts (7)[C].

- Intravitreal corticosteroid injections are used only in severe cases of recurrence; triamcinolone acetonide 4 to 20 mg/0.1 mL, dexamethasone phosphate 0.4 mg/0.1 mL, dexamethasone implant (Ozurdex).

  Ozurdex has a longer effect than triamcinolone acetonide.

- Immunosuppressive agents including antimetabolites (methotrexate, azathioprine, and mycophenolate mofetil), T-cell inhibitors (cyclosporine, tacrolimus, and sirolimus), and alkylating agents (cyclophosphamide, chlorambucil) may be employed in cases resistant to initial treatment, but close monitoring is required (6),(7)[C].

  Advancing research suggests benefit of the biologic agents in refractory uveitis. Adalimumab has gained FDA approval for this indication. Some expert panels recommend adalimumab and infliximab as second-line therapy options. Other biologic agents including golimumab, abatacept, and tocilizumab have also been studied.

  Benefits of biologic therapy include glucocorticoid sparing effects, but limitations may include high cost and adverse effect potential (5),(6)[C].

ISSUES FOR REFERRAL

Caution should be used when using empiric treatment; referral to an ophthalmologist is recommended in most cases.

SURGERY/OTHER PROCEDURES
Various surgical procedures may be used therapeutically for visual rehabilitation, diagnostically, or to manage complications associated with uveitis (8).

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Complete history and physical to evaluate for associated systemic disease
- Ophthalmologic follow-up as recommended by consultant

**PATIENT EDUCATION**
- Instruct on proper method for instilling eye drops.
- Wear dark glasses if photophobia is a problem.

**PROGNOSIS**
- Depends on the presence of causal diseases or associated conditions
- Uveitis resulting from infections (systemic or local) tends to resolve with eradication of the underlying infection.
- Uveitis associated with seronegative arthropathies tends to be acute (lasting <3 months) and frequently recurrent.

**COMPLICATIONS**
- Cycloplegia: paralysis of the ciliary muscle of the eye, resulting in a loss of accommodation
- Loss of vision as a result of the following:
  - Keratic precipitates deposition on the corneal or lens surfaces (2)
  - Increased intraocular pressure, acute angle-closure glaucoma (2)
  - Formation of synechiae
  - Cataract formation (2)
  - Vasculitis with vascular occlusion, retinal infarction
  - Macular edema (2)
  - Optic nerve damage

CODES

ICD10

- H20.9 Unspecified iridocyclitis
- H30.90 Unspecified chorioretinal inflammation, unspecified eye
- H20.019 Primary iridocyclitis, unspecified eye

CLINICAL PEARLS

- Symptoms vary depending on depth of involvement and associated conditions but should be suspected when eye pain is associated with visual changes.
- Severe or unresponsive uveitis may require therapy, including periocular injection of corticosteroids, sustained-release corticosteroid implants, systemic corticosteroids, cytotoxic agents, immunosuppressive agents, immunomodulatory agents, or tumor necrosis factor inhibitors.
VAGINAL ADENOSIS
Maeve K. Hopkins, MD • Michael P. Hopkins, MD, MEd

BASICS

DESCRIPTION
• The normal vagina is lined with squamous epithelium. Adenosis is characterized by the presence of columnar epithelium or glandular tissue in the wall of the vagina.
• Around week 15 of embryologic development, the müllerian system, which forms the upper 2/3 of the vagina, fuses with the invaginating cloaca or urogenital sinus to form the lower 1/3 of the vagina. Squamous metaplasia from the cloacal region then produces squamous epithelium within the vagina (1).
• Adenosis occurs when this squamous epithelium fails to epithelialize the vagina completely.
• Three main types of adenosis epithelium:
  – Endocervical
  – Endometrial
  – Tubal
• System(s) affected: reproductive

Geriatric Considerations
• Adenosis is a disorder of the young female. By menopause, the vagina and cervix should be completely epithelialized.
• In a postmenopausal patient, the presence of glandular epithelium is an indication for excision and evaluation, given the risk of well-differentiated adenocarcinoma.

Pregnancy Considerations
Pregnancy produces a wide eversion of the transformation zone of the cervix. This can become so widely everted that it will extend onto the vaginal fornices, leading to the impression of adenosis. This will resolve after pregnancy.

EPIDEMIOLOGY

Incidence
• Although the cumulative incidence of vaginal adenosis is unknown, the incidence of cloacal malformations is 1/20,000 to 1/25,000 live births.
• Although spontaneous vaginal adenosis appears to be fairly common (10% of adult women), it is mostly an insignificant coincidental finding. Widespread symptomatic involvement is rare (2).

Prevalence
• In the United States, adenosis is common in young women, affecting 10–20%. As maturation progresses with puberty, epithelialization occurs.
• Predominant age
  – Age <1 month: 15%
  – Prepubertal: typically absent
  – Age 13 to 25 years: 13%
  – Age >25 years: decreasing prevalence, uncommon beyond age 30 years (2)
ETIOLOGY AND PATHOPHYSIOLOGY

- In most young females, the etiology is incomplete squamous metaplasia or epithelialization. This occurs as a natural phenomenon and resolves with age.
- Described as congenital or acquired:
  - Congenital: proliferation of the remnant müllerian epithelium in the vagina due to exposure to diethylstilbestrol (DES) in utero ("DES daughters"). DES is a synthetic, nonsteroidal estrogen used to prevent miscarriage or premature deliveries from 1938 to 1971 (3). An estimated 5 million women were prescribed DES during this period (4).
  - Transformation-related protein 63 (TRP63/p63) marks the cell fate of müllerian duct epithelium to become squamous epithelium in the cervix and vagina. DES disrupts the TRP63 expression and induces adenosis lesions (4). It has also been suggested that DES induces vaginal adenosis by inhibiting the BMP4/activin A-regulated vaginal cell fate through a downregulation of RUNX1 (5).
  - Acquired: trauma and inflammation causing spontaneous de novo changes or changes in an acquired lesion in the vaginal epithelium
  - Additional reports documented adenosis subsequent to sulfonamide-induced Stevens-Johnson syndrome and after treatment of vaginal condylomas with 5-fluorouracil (6).

RISK FACTORS

Adenosis of the vagina/cervix may arise in up to 90% of DES daughters and has a 40-fold increased risk of developing into clear cell adenocarcinoma (3).

GENERAL PREVENTION

None: Last DES exposure was in the 1970s.

COMMONLY ASSOCIATED CONDITIONS

DES exposure
- Adenosis from DES exposure should lead to an evaluation of other DES-related abnormalities.
- Müllarian tract anomalies associated with DES exposure include cervical hood, cervical ridge, shortened cervix, incompetent cervix, and T-shaped uterine cavity.
- Patients with known DES exposure should have their reproductive tract evaluated prior to conception.
- Most patients with adenosis have not been DES-exposed and do not require evaluation of the reproductive system.
- The FDA issued a drug bulletin in 1971 advising physicians to stop prescribing DES to pregnant women because of its link to vaginal clear cell adenocarcinoma in DES daughters (3).

DIAGNOSIS

HISTORY
- Maternal DES exposure
- Complaints of
  - Profuse mucoid vaginal discharge from the glandular epithelium
  - Pruritus
  - Pain/soreness of the vaginal introitus
– Postcoital bleeding
– Dyspareunia

PHYSICAL EXAM
On pelvic exam, adenosis appearance is varied: patchy or diffuse red stippling, granularity or nodularity, single or multiple cysts, erosions, ulcers, or warty protuberances that may even extend to the vulva.

DIFFERENTIAL DIAGNOSIS
- Erosive lichen planus
- Fixed drug eruption
- Erythema multiforme
- Bullous skin disease
- Adenocarcinoma

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
Four-quadrant Pap smear should be used liberally to isolate quadrants of the vagina that may contain abnormalities. No imaging is indicated, unless diagnosed with underlying malignancy.

Follow-Up Tests & Special Considerations
Pap smear can be followed by colposcopy and biopsy.

Diagnostic Procedures/Other
- Colposcopy should be used to outline areas of adenosis to ensure that no malignancy is present.
- A thorough evaluation for adenocarcinoma of the vagina arising in adenosis should be done.
- A biopsy may be necessary to ensure that the process represents only benign adenosis.

Test Interpretation
- Biopsy will show benign glandular epithelium.
- Biopsies may show areas of ongoing squamous metaplasia.

TREATMENT

GENERAL MEASURES
- Unless malignancy is present, treatment is conservative.
- In most young females with this condition, it will resolve with expectant management.
- Treatment is warranted in women with severe subjective symptoms that impair the quality of life.
- First-line treatment: If indicated in patients with focal lesions and no history of DES exposure, simple excision is an effective treatment (6).

ISSUES FOR REFERRAL
Malignancy found on biopsy warrants referral to gynecologic oncology specialist.

SURGERY/OTHER PROCEDURES
- Aggressive therapy, such as laser or surgical excision, is necessary if premalignant or
malignant changes arise (5).
- Symptomatic treatment has been performed with carbon dioxide laser coagulation, unipolar coagulation, or vaginal resection.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Outpatient management

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
If the initial colposcopy is normal, a yearly four-quadrant Pap smear of the vagina and of the cervix should be performed.

DIET
No special diet is recommended.

PATIENT EDUCATION
- No limitations
- It is not necessary to avoid intercourse or placing objects in the vagina.
- The patient should be educated to keep normal guideline-recommended pelvic and Pap smear appointments. In most situations, this is benign, and expectant management is all that is necessary.
- http://www.acog.org/

PROGNOSIS
- Most patients will have squamous metaplasia and epithelialization with complete resolution of the adenosis.
- The rare patient, 1/1,000 to 1/10,000, may develop adenocarcinoma in the adenosis and will require definitive therapy as for vaginal cancer.
  - Cumulative incidence of progression of adenosis to adenocarcinoma is 1.5/1,000 for DES daughters (3).

COMPLICATIONS
- Infertility with DES association
- Adverse pregnancy outcome with DES association
- Adenocarcinoma of vagina
- Clear cell adenocarcinoma with DES association

Vaginal Malignancy

**CODES**

**ICD10**

- Q52.4 Other congenital malformations of vagina
- N89.8 Other specified noninflammatory disorders of vagina
- T38.5X5A Adverse effect of other estrogens and progestogens, initial encounter

**CLINICAL PEARLS**

- Adenosis is characterized by the presence of columnar epithelium or glandular tissue in the wall of the vagina.
- Adenosis is common among the daughters of women exposed to DES.
- Rarely, adenosis can be associated with an underlying vaginal malignancy.
VAGINAL BLEEDING DURING PREGNANCY
Virginia J. Van Duyne, MD

BASICS

DESCRIPTION
• Vaginal bleeding during pregnancy has many causes and ranges in severity from benign with normal pregnancy outcome to life-threatening for both infant and mother.
• Etiology can be from the vagina, cervix, uterus, fetus, or placenta. The differential diagnosis is guided by the gestational age of the fetus.

EPIDEMIOLOGY

Prevalence
• In early pregnancy: 7–25% of patients
• In late pregnancy: 0.3–2% of patients

ETIOLOGY AND PATHOPHYSIOLOGY
• Many times the cause is unknown.
• Anytime in pregnancy:
  – Cervicitis (infectious or noninfectious)
  – Vaginal or cervical trauma (including postcoital)
  – Cervical lesion or neoplasia
  – Hyperemia of cervix (increased blood flow from pregnancy)
• Early pregnancy:
  – For up to 50% of early pregnancy bleeding, no cause is ever found.
  – Ectopic pregnancy: leading cause of 1st-trimester maternal death in the United States. Risk factors: previous ectopic, trauma to fallopian tubes (tubal surgery, infection, tumor), congenital anomaly of tubes, in utero diethylstilbestrol (DES) exposure, current use of IUD, history of infertility, tobacco use
  – Spontaneous abortion: risk factors: advanced maternal age (AMA), alcohol use, tobacco use, anesthetic gas, heavy caffeine use, cocaine use, chronic maternal diseases (poorly controlled diabetes mellitus [DM], celiac disease, autoimmune diseases such as antiphospholipid syndrome), short interconception time (3 to 6 months), current use of IUD, maternal infection (e.g., herpes simplex virus [HSV], gonorrhea, chlamydia, toxoplasmosis, listeriosis, HIV, syphilis, malaria), medications (e.g., retinoids, methotrexate, NSAIDs), multiple previous therapeutic abortions, previous spontaneous abortion, toxins (arsenic, lead, polyurethane), uterine abnormalities (congenital, adhesions, fibroids)
  – Implantation bleeding: benign, about 6 days after fertilization
  – Uterine fibroids
  – Subchorionic bleeding: in late 1st trimester
  – Low-lying placenta
  – Gestational trophoblastic disease: hydatidiform mole (most common), choriocarcinoma, or placental-site trophoblastic tumors
• Late pregnancy:
  – Bloody show of labor (mucus plug)
– Placenta previa: painless bleeding; occurs in 0.4% deliveries in the United States. Risk factors: previous history of placenta previa, previous uterine surgery (cesarean section, D&C), chronic hypertension, multiparity, multiple gestation, tobacco use, AMA
– Placental abruption: (typically) painful bleeding; occurs in 1–2% deliveries in the United States. Risk factors: previous placental abruption, 1st-trimester bleeding, hypertension, preeclampsia, multiple gestation, tobacco, cocaine or methamphetamine use, unexplained elevated maternal α-fetoprotein, poly- or oligohydramnios, AMA, trauma to abdomen, premature rupture of membranes, thrombophilia, short umbilical cord, male fetus, chorioamnionitis, nutritional deficiency
– Vasa previa: minimal bleeding with fetal distress; rare (1:2,500 deliveries). Risk factors: in vitro fertilization, multiple gestations, placental abnormalities (low-lying position, bilobate, succenturiate lobe, velamentous insertion of umbilical cord)
– Placenta accreta, increta, percreta: risk factors: uterine scar (e.g., from cesarean section, endometrial ablation, or D&C), current placenta previa, AMA, tobacco use, multiparity, uterine anomalies, uterine fibroids, hypertension
– Uterine rupture: vaginal bleeding, abnormal fetal heart rate, and disordered or hypertonic uterine contractions with or without pain. Risk factors: previous cesarean section (most common), trauma, use of oxytocin or prostaglandins, multiparity, external cephalic version, placental abruption, shoulder dystocia, placenta percreta, müllerian duct anomalies, history of pelvic radiation

RISK FACTORS
See specific etiologies in earlier discussion.

GENERAL PREVENTION
- Address modifiable risk factors such as domestic violence and tobacco and drug use.
- If placenta or vasa previa, nothing per vagina

DIAGNOSIS

HISTORY
- Anytime in pregnancy: quality of pregnancy dating, context (e.g., following bowel movement, during voiding, after intercourse, drug use, or trauma including domestic violence), amount of bleeding, obstetrical history, personal or family history of inherited bleeding disorders
- Early pregnancy: severe nausea/vomiting (can be associated with molar pregnancy); amount of bleeding, pelvic pain, or suprapubic cramping (e.g., spontaneous abortion, ectopic) complications in previous pregnancies (e.g., spontaneous abortion, abruption, 1st-trimester vaginal bleeding)
- Late pregnancy: contractions (labor), abdominal pain especially between contractions (abruption, uterine rupture), presence or absence of fetal movement, rupture of membranes
- See “Etiology and Pathophysiology” for additional pertinent history.

PHYSICAL EXAM
- Vital signs: When present, signs of hemodynamic instability are first tachycardia and tachypnea and then hypotension and thready pulse.
- Abdomen: uterine tenderness, fundal height (increasing fundal height may be associated with placental abruption)
Speculum: Visualize cervix and identify source of bleeding (from cervical os or from within vagina).
Cervix: Assess for dilation; required to assess for labor but should not be performed until placenta previa ruled out via ultrasound
Fetal monitoring: Doppler heart tones in early pregnancy; external fetal monitoring for gestational age >26 weeks

DIFFERENTIAL DIAGNOSIS
- Hematuria (UTI, kidney stones)
- Rectal bleeding

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- CBC
- Blood type and screen; if significant hemorrhage, type and cross-match
- Quantitative β-human chorionic gonadotropin (β-hCG):
  - Prior to 12 weeks, levels can be followed serially every 2 days with following trends:
    - Doubles or at least 66% rise in 48 hours in normal pregnancy
    - Falls in spontaneous abortion
    - Extremely high in molar pregnancy
    - Rises gradually (<50% in 48 hours) or plateaus in ectopic pregnancy
- Transvaginal ultrasound should be used to confirm an intrauterine pregnancy (IUP) when the quantitative β-hCG >2,000 (1)[A].
- Other lab tests based on clinical scenario:
  - Wet mount, gonorrhea/chlamydia, Pap smear
  - Progesterone level occasionally used to determine viability in threatened abortion (<5 indicates not viable, >25 indicates viability, 5 to 25 is equivocal)
  - Bleeding time, fibrinogen, and fibrin split products: if suspect coagulopathy or abruption
  - Kleihauer-Betke: low sensitivity and specificity for abruption; helpful for dosing RhoGAM
- Ultrasound is the preferred imaging modality.
  - Early pregnancy:
    - Gestational sac seen at 5 to 6 weeks; fetal heartbeat observed by 8 to 9 weeks
    - Diagnostic of ectopic with nearly 100% sensitivity when β-hCG level 1,500 to 2,000 mIU/mL. If no IUP is present and ultrasound does not confirm ectopic pregnancy, serial quantitative β-hCG values should be followed (2)[C].
  - Late pregnancy:
    - Proceed to rule out placenta previa with ultrasound, labor with serial cervical exams, and abruption with external fetal monitoring.

ALERT
Confirm fetal presentation and placental position prior to cervical exam.

TREATMENT

MEDICATION
First Line
Treat underlying cause of bleeding, if identified.
- If mother is Rh-negative, give RhoGAM to prevent autoimmunization. In late pregnancy, dose according to the amount of estimated fetomaternal hemorrhage.
- If cause of bleeding is preterm labor, consider betamethasone for fetal lung maturity if <36 weeks’ gestation. Tocolytics may be used to prolong pregnancy to allow for course of steroids.
- If threatened abortion: Consider progesterone (relative risk 0.53) (3)[A].
- If mother has an inherited bleeding disorder or if bleeding is severe, consider recombinant or donor blood products.

SURGERY/OTHER PROCEDURES
- Cesarean section may be indicated for recurrent or uncontrolled bleeding with placenta or vasa previa.
- If ectopic is diagnosed, immediate surgical treatment may be needed. Some early ectopic pregnancies can be treated medically if certain criteria are met (2)[C].
- Surgical uterine evacuation is necessary for molar pregnancy due to malignant potential (4)[C].
- Incomplete or inevitable spontaneous abortion: Management is patient centered. In the absence of infection, patient may elect expectant, medical, or surgical management. If expectant management, typically wait 2 weeks for patient to complete abortion; most complete by 9 days. If at 2 weeks abortion is not completed or medical management has failed, surgical intervention (D&C or aspiration) is generally indicated (5)[A]; may send tissue to pathology to confirm

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- In early pregnancy: based on quantity of bleeding, need for surgical treatment for ectopic pregnancy, or presence of infection in case of spontaneous abortion
- In late pregnancy, if significant bleeding and/or presence of maternal or fetal compromise
- In late pregnancy with trauma, if ≥2 contractions per 10 minutes
- In late pregnancy, may discharge when bleeding has stopped; labor, previa, and abruption have been ruled out; and fetal heart tracing is normal.
- After trauma in late pregnancy, may discharge home if normal fetal heart tracing for ≥4 hours with <2 contractions per 10 minutes

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Patient should be instructed to report any increase in the amount or frequency of bleeding and to seek immediate care if experiencing fever, abdominal pain, or sudden increased bleeding. Patient should save any tissue passed vaginally for examination.
- Frequency of outpatient follow-up as indicated based on etiology of bleeding

PATIENT EDUCATION
- American College of Obstetricians and Gynecologists (ACOG): https://www.acog.org/

PROGNOSIS
Prognosis depends on the etiology of vaginal bleeding, severity of bleeding, and rapidity of diagnosis.

• Maternal mortality is 31.9 deaths per 100,000 ectopic pregnancies.

• 1/2 of patients with early pregnancy bleeding miscarry; if fetal heart activity (ultrasound) present in 1st-trimester bleeding, <10% chance of pregnancy loss.

• Heavy bleeding in early pregnancy, particularly when accompanied by pain, is associated with higher risk of spontaneous abortion. Spotting and light episodes are not, especially if lasting only 1 to 2 days.

• Subchorionic hemorrhage has about 2- to 3-fold increased risk of spontaneous abortion. Smaller hemorrhage and presence of viable fetal heart rate confer lower risk of loss; most resolve spontaneously.

• Women with early pregnancy bleeding have an increased risk of preterm delivery, premature rupture of membranes, manual removal of placenta, placental abruption, elective cesarean delivery, and term labor induction later in the same pregnancy. These women also have an increased risk of adverse pregnancy outcomes, including hyperbilirubinemia, congenital anomalies, NICU admission, and reduced neonatal birth weight. Finally, there is an increased risk in subsequent pregnancies of recurrence of early pregnancy bleeding.

• Bed rest has not been shown to affect the outcome of bleeding in early pregnancy but may be indicated for bleeding in late pregnancy with placenta or vasa previa or with maternal hypertension.

CODES
ICD10
- O20.9 Hemorrhage in early pregnancy, unspecified
- O46.90 Antepartum hemorrhage, unspecified, unspecified trimester
- O20.0 Threatened abortion

CLINICAL PEARLS
- Obtain blood type and screen all women presenting with vaginal bleeding in pregnancy and administer RhGAM to all Rh-negative patients.
- For up to 50% of early pregnancy bleeding, no cause is ever found.
- Always consider ectopic pregnancy in 1st-trimester bleeding.
- Do not perform digital exam in late pregnancy bleeding until placenta has been located on ultrasound.
**VAGINAL MALIGNANCY**
Michael P. Hopkins, MD, MEd

### BASICS

#### DESCRIPTION
- Carcinomas of the vagina are uncommon: 2–3% of gynecologic malignancies, 2,300 new cases annually.
- Vaginal intraepithelial neoplasia (VAIN), defined by squamous cell atypia, is classified by the depth of epithelial involvement:
  - VAIN 1: 1/3 thickness
  - VAIN 2: 2/3 thickness
  - VAIN 3 and carcinoma in situ (CIS): >2/3
  - CIS, designating full-thickness neoplastic changes without invasion through the basement membrane
- Invasive malignancies: Vaginal malignancies include squamous cell carcinoma (85–90%), adenocarcinoma (5–10%), sarcoma (2–3%), and melanoma (2–3%). Clear cell carcinoma is a subtype of adenocarcinoma. Invasive squamous cell carcinoma has the potential for metastasis to the lungs and liver.
- To be classified as a vaginal malignancy, only the vagina can be involved. If the cervix or vulva is involved, then the tumor is classified as a primary cancer arising from the cervix or the vulva.
- Most vaginal malignancies are metastatic (e.g., cervix, vulva, endometrium, breast, ovary).
- Most common sites of metastases: lung, liver, bone

#### Pregnancy Considerations
This malignancy is not associated with pregnancy.

### EPIDEMIOLOGY

#### Incidence
Predominant age
- CIS: mid-40 to 60 years
- Invasive squamous cell malignancy: mid-60 to 70 years
- Adenocarcinoma: any age; 50 years is the mean age. Peak incidence is between 17 and 21 years of age.
- Clear cell adenocarcinoma occurs most often in females <30 years with a history of exposure to diethylstilbestrol (DES) in utero.
- Mixed müllerian sarcomas and leiomyosarcomas in the adult population: mean age 60 years

#### Pediatric Considerations
Vaginal tumors are extremely rare. Rhabdomyosarcoma (botryoid and embryonal subtype) is the most common malignant neoplasm of the vagina. Less common entities are germ cell tumor and clear cell adenocarcinoma.

#### Prevalence
In the United States, it is one of the rarest of all gynecologic malignancies (3%).
ETIOLOGY AND PATHOPHYSIOLOGY

- Women with a history of cervical malignancy have a higher probability of developing squamous cell malignancy in the vagina even after hysterectomy.
- Human papillomavirus (HPV) is found in 80–93% of patients with vaginal CIS and 50–65% of the patients with invasive vaginal carcinoma.
- HPV-16 is the most common, found in 66% of CIS and 55% of invasive vaginal cancers.
- Smokers have a higher incidence.
- Clear cell adenocarcinoma of the vagina in young women has been associated with DES exposure. The incidence, however, is exceedingly rare, estimated at 1/1,000 to 1/10,000 exposed females.
- Metastatic lesions can involve the vagina, spreading from the other gynecologic organs.
- Although rare, renal cell carcinoma, lung adenocarcinoma, GI cancer, pancreatic adenocarcinoma, ovarian germ cell cancer, trophoblastic neoplasm, and breast cancer can all metastasize to the vagina.

Genetics

No known genetic pattern

RISK FACTORS

- Similar risk factors as cervical cancer
- Age
- African American
- Smoking
- Multiple sex partners, early age of first sexual intercourse
- History of squamous cell cancer of the cervix or vulva
- HPV infection
- Vaginal adenosis
- Vaginal irritation
- DES exposure in utero
- Immunocompromised, HIV
- Prior pelvic radiation

COMMONLY ASSOCIATED CONDITIONS

Due to the field effect, patients with vaginal cancer are more likely to develop malignancy in the cervix or vulva and should be followed closely.

DIAGNOSIS

HISTORY

- Abnormal bleeding is the most common symptom.
- Postcoital bleeding can result from direct trauma to the tumor.
- Vaginal discharge
- Dyspareunia
- Urinary symptoms, including hematuria and increased frequency
- Constipation
- Pain along with symptoms and signs of hydroureter are late findings when the tumor has
spread into the paravaginal tissues and extends to the pelvic sidewall (1)[A].

Pediatric Considerations
In children, sarcomas can present either as a mass protruding from the vagina or as abnormal genital bleeding (1)[A].

PHYSICAL EXAM
Pelvic examination
- The vagina, uterus, adnexa (fallopian tubes and ovaries), bladder, and rectum should be evaluated for unusual changes.
- Vaginal malignancies are found most commonly on the posterior wall in the upper 1/3 of the vagina.

DIFFERENTIAL DIAGNOSIS
- Premalignant changes: VAIN 1, 2, 3, and CIS
- Adequate biopsies ensure that invasive lesions are not overlooked. Invasive lesions penetrate the basement membrane and cannot be treated conservatively.
- Other malignancies, such as endometrial, cervix, bladder, or colon cancer, can invade directly into the vagina or metastasize to the vagina.
- In the childbearing years, trophoblastic disease should be considered.
  - The vagina is a common site of metastases; however, biopsy should typically be avoided because the implants are very vascular and may hemorrhage if sampled.
  - The clinical presentation is typically obvious so histopathologic confirmation before treatment is not required.

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Pap smear may incidentally detect asymptomatic lesions.
- Biopsy suspicious lesions
- Chest x-ray (CXR): to evaluate for metastatic disease
- CT scan and MRI: to evaluate the liver and retroperitoneum, especially the lymph nodes in the pelvic and periaortic area
- PET scan detects primary and secondary metastatic lesions more often than CT scan.

ALERT
PET scan correlation with CT scan lesions strongly suggests malignancy.

Follow-Up Tests & Special Considerations
- Lymphoscintigraphy (sentinel lymph node mapping) as part of the pretreatment evaluation can result in a change in the radiation fields and improve comprehensive treatment planning in women with vaginal cancer.
- HPV vaccination: Implementation of prophylactic HPV vaccination could prevent ~2/3 of the intraepithelial lesions in the lower genital tract but is yet proven.

Diagnostic Procedures/Other
- Colposcopy with directed biopsies for small lesions
- Wide excision under anesthesia of superficial disease may be necessary to ensure that invasive cancer is not present.
Cystoscopy to rule out bladder invasion
Proctosigmoidoscopy to rule out rectal invasion

**Test Interpretation**

Tumors are staged clinically:
- **Stage 0:** VAIN and CIS
- **Stage I:** carcinoma limited to the vaginal wall (26%)
- **Stage II:** involves the subvaginal tissues but has not extended to the pelvic wall (37%)
- **Stage III:** extends to the pelvic wall (24%)
- **Stage IV:** extends beyond the true pelvis (13%)
  - IVa: Tumor invades bladder and/or rectal mucosa and/or direct extension beyond the true pelvis.
  - IVb: spread to distant organs

**TREATMENT**

**GENERAL MEASURES**

Treatment methods for VAIN and CIS include the following:
- Wide local excision
- Partial or total vaginectomy
- Intravaginal chemotherapy with 5% fluorouracil cream
- Laser therapy
- Intracavitary radiation therapy

**MEDICATION**

- Imiquimod
  - In a review of the effectiveness of 5% imiquimod cream in the treatment of VAIN, the following results were reported (2)[C]:
    - 26–100% of patients had complete regression.
    - 0–60% of patients had partial regression.
    - 0–37% experienced recurrence.
- Contraindications
  - The diagnosis must be established with certainty prior to treatment.
  - If there is any doubt that a process beyond in situ disease exists, vaginectomy must be performed. These patients are often elderly, and aggressive therapy is limited by the patient’s performance status and ability to tolerate radical surgery, chemotherapy, or radiation.

**ISSUES FOR REFERRAL**

Patients should be treated by a gynecologic oncologist and/or a radiation oncologist.

**ADDITIONAL THERAPIES**

- Treatment with radiotherapy depends on the stage of disease. This treatment option should be discussed with physicians experienced with this malignancy.
- It is common to use radiotherapy and chemotherapy (chemoradiation) for better cancer control.
- Early-stage primary squamous cell carcinoma treated with radiation alone has shown good results.
Stage III vaginal cancer may benefit from combined radiation and hyperthermia (1)[C].
Patients with advanced squamous cell carcinoma or adenocarcinoma receive concurrent irradiation and cisplatin-based chemotherapy.
Neoadjuvant chemotherapy followed by radical surgery may benefit selected patients (3)[C].
In most tumor types, metastatic disease from the vagina to other sites is only minimally responsive to chemotherapy.
With one exception, no chemotherapeutic agents have shown a survival advantage. The exception is childhood sarcomas, which have been treated with combinations of the following:
- Vincristine
- Dactinomycin (actinomycin-D)
- Cyclophosphamide (Cytoxan)
- Cisplatin
- Etoposide (VP-16)

**SURGERY/OTHER PROCEDURES**
Whenever there is a doubt as to the presence or absence of invasive disease, vaginectomy must be performed.
Invasive lesions usually are treated by radiation therapy, but stage I lesions can be treated with radical hysterectomy or radical vaginectomy with pelvic lymph node dissection (2)[A].
If the lesion involves the lower vagina, inguinial node dissection also must be done because cancer involving the lower vagina can metastasize to the groin region (inguinal–femoral nodes).
Premenopausal women who desire to retain ovarian function are better candidates for radical surgery for early-stage disease, with vaginal reconstruction possible afterward.
Patients who have not completed their family can occasionally be treated with limited resection and localized radiation to the area (4)[A].
Sarcomas are treated by radiation therapy followed by pelvic exenteration if persistent disease is present.

**Pediatric Considerations**
The treatment of vaginal tumors today mainly consists of neoadjuvant chemotherapy followed by local control with surgery or radiotherapy (1)[A].

**Geriatric Considerations**
Older patients, many with a long history of smoking, are at a higher risk for malignancies requiring surgical treatments.

---

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Patients are usually ambulatory and able to resume full activity by 6 weeks after surgery.
- Most patients are fully active while receiving chemotherapy and radiation therapy.

**Patient Monitoring**
- Pelvic examination and Pap smear every 3 months for 2 years, then every 6 months for the next 3 years, and then yearly thereafter
- Annual CXR
PATIENT EDUCATION
- Printed patient information available from American College of Obstetricians and Gynecologists, 409 12th St., SW, Washington, DC 20024-2188; 800-762-ACOG: http://www.acog.org
- American Cancer Society: http://www.cancer.gov

PROGNOSIS
Stage and 5-year survival (5)
- I: 77.6%
- II: 52.2%
- III: 42.5%
- IVA: 20.5%
- IVB: 12.9%
- Stage is the most important determinant of survival (4).
- Tumor size >2 cm, correlated with worse survival outcome

COMPLICATIONS
- Those typically associated with major abdominal surgery or radiation therapy
- Common complications of treatment include rectovaginal or vesicovaginal fistulas, rectal/vaginal strictures, radiation cystitis, and/or proctitis.
- Most recurrences occur within the first 2 years after initial diagnosis.

REFERENCES

ADDITIONAL READING
CODES

**ICD10**
- C52 Malignant neoplasm of vagina
- D07.2 Carcinoma in situ of vagina
- N89.3 Dysplasia of vagina, unspecified

**CLINICAL PEARLS**
- Vaginal cancer is rare; 85–90% of vaginal cancers are squamous cell.
- Vaginal malignancies are found most commonly on the posterior wall in the upper 1/3 of the vagina.
- Most vaginal malignancies are metastatic (from cervix, vulva, endometrium, breast, or ovary).
VAGINITIS AND VAGINOSIS
KrisEmily McCrory, MD, FAAFP

BASICS

DESCRIPTION

- “Vaginosis” and “vaginitis” are broad terms indicating any disease process of the vagina caused by or leading to infection, inflammation, or changes in the normal vaginal flora.
- The difference between vaginitis and vaginosis is the presence (vaginitis) or absence (vaginosis) of inflammation.
- The most common symptoms of vaginitis/vaginosis are vaginal discharge, odor, itching, burning, or pain.
- The most common causes of vaginitis/vaginosis are bacterial vaginosis (BV), vulvovaginal candidiasis (VVC), and trichomoniasis.
- Other causes of vaginitis can be stratified by age and are generally associated with postmenopausal vaginal atrophy or foreign bodies in the pediatric population.
- Lichen planus, lichen sclerosus, psoriasis, and contact/allergic dermatitis may also cause vaginitis.
- Diagnosis of vaginitis relies on thorough history, physical exam, and clinical assessment.
  Microscopy, cultures, DNA probes, and tissue biopsy can be helpful in confirming diagnosis.
- BV is the most common cause of vaginal discharge in reproductive-age women. It is caused by a disturbance in the normal vaginal flora. The normally dominant hydrogen peroxide–producing lactobacilli are overwhelmed by an overgrowth of gram-negative species causing an increase in the vaginal pH, discharge, and odor.
- VVC is the second most common cause of vaginitis in reproductive-age women. It is caused by invasion of the Candida organism into the superficial epithelial cells of the vagina causing mild to severe vaginal inflammation, pruritus, and discharge.

EPIDEMIOLOGY

- Vaginal symptoms are typical and common in the general population and are one of the most frequent reasons women present to their medical care providers accounting for approximately 10 million office visits each year.
- About 30% of women with complaint of vaginal discharge or irritation remain undiagnosed despite extensive testing.
- In the United States, BV continues to be the leading cause of vaginal complaints. The frequency of VVC is highest among women in their reproductive years.
- Neither vaginal candidiasis nor BV is considered to be a sexually transmitted infection.
- Vaginal trichomoniasis is a common sexually transmitted disease with 7.4 million cases diagnosed yearly in the United States and is the most common curable, nonviral sexually transmitted infection worldwide.

ETIOLOGY AND PATHOPHYSIOLOGY

- BV
  - BV is caused by a change in the normal vaginal flora. Dominant lactobacilli responsible for maintaining the acidic vaginal pH are overcome by an increase of the gram-negative
organisms.
- Change in the vaginal environment leads to an increase in the pH and an overgrowth of vaginal anaerobes, causing a malodorous, clear, white, or gray discharge and a fishy odor.
- BV is highly prevalent and associated with multiple adverse outcomes, including enhanced HIV transmission.
- The organisms generally implicated in BV infections include:
  - *Gardnerella vaginalis*
  - *Prevotella* species
  - *Porphyromonas* species
  - *Bacteroides* species
  - *Peptostreptococcus* species
  - *Mycoplasma hominis*
  - *Ureaplasma urealyticum*
  - *Mobiluncus* species
  - *Fusobacterium* species
  - *Atopobium vaginae*
- **VVC**
  - VVC is caused by *Candida albicans* (80–92%) and *Candida glabrata* (<10%).
  - Candida organisms can be identified in the lower genital tract in healthy women, and it is thought to gain access via rectal and perianal colonization and migration.
  - Symptoms occur when candidal organisms overwhelm the normal vaginal flora and invade the superficial vaginal epithelial cells, causing inflammation, pruritus, and thick vaginal discharge.
  - Complicated VVC should be considered in pregnant patients, patients with diabetes, or immunocompromising conditions. Patients who experience four or more episodes of VVC in a year or who have only budding yeast on wet mount may also be considered to have complicated VVC.
- **Trichomoniasis**
  - Caused by an infection via *Trichomonas vaginalis*, a flagellate protozoan. The organism infects the squamous epithelium of the vagina as well as the urethra and paraurethral glands. This infection is primarily transmitted during sexual intercourse.
- **Desquamative inflammatory vaginitis (DIV)**
  - A chronic, purulent vaginitis occurring most commonly in the perimenopause
  - Etiology and pathogenesis uncertain
  - Diagnosis of exclusion. Estrogen deficiency should be considered and addressed.
- **Other sources of vaginitis/vaginosis** are usually mediated by disruption of the vaginal squamous epithelium. This disruption can lead to inflammation, pain, and discharge.
  - Other than the three most common causes of vaginitis/vaginosis, menses, sexual activity, contraception, pregnancy, foreign bodies, estrogen levels, STDs, and use of vaginal hygiene products, topical creams, or antibiotics can contribute to vaginal symptoms.

**RISK FACTORS**
- **BV**
  - Sexual activity; although BV is not considered an STD, studies show increased rates of BV in women with multiple sex partners.
  - Women who have sex with women
  - Smoking
– Vaginal douching
– The presence of STDs such as HSV-2 (1)

*VVC*
– Diabetes
– Diet high in refined sugars
– Use of broad-spectrum antibiotics
– Immunosuppression
– Higher estrogen levels have been associated with increased vaginal yeast infection, explaining why it is more commonly diagnosed in reproductive-age women and in pregnancy.

*Trichomoniasis*
– Inconsistent use of barrier contraception
– Multiple sex partners
– Limited education and low socioeconomic status
– Illicit drug use
– Smoking

Other risk factors associated with vaginitis/vaginosis:
– Decreased estrogen
– Smoking
– Use of vaginal douches and creams
– Tight-fitting clothing
– Poor hygienic practice
– Changes in diet

**GENERAL PREVENTION**
● Vulvar hygiene with warm water and unscented cleanser.
● Do not use hair dryer to dry vulva.
● Wear cotton underwear.
● Except in cases of trichomoniasis, treatment of sexual partners generally is not recommended but may be considered in recurrent cases.
● Advise patients not to douche.

**COMMONLY ASSOCIATED CONDITIONS**
● STDs such as gonorrhea, chlamydia, or HSV
● Vaginal intraepithelial neoplasia and cancer can present with symptoms of vaginitis.
● DIV presents with similar symptoms but most commonly occurs in postmenopausal women.

**DIAGNOSIS**

**HISTORY**
● General principles:
  – The key to diagnosis is clarification of the presenting symptoms.
  – Onset, timing, and character of the vaginal symptoms are important questions to ask.
  – Many patients will be asymptomatic.
  – Diagnosis is made on routine physical exam and in-office lab testing including microscopy and vaginal pH testing.
– Pap smears should not be used as diagnostic tools due to low sensitivity and specificity.
– Symptomatic patients generally complain of itching, burning, irritation, and abnormal discharge.

• **BV**
  – Symptomatic patients complain of abnormal vaginal discharge and a fishy odor.
  – Pain and pruritus are uncommon.

• **VVC**
  – Symptomatic women report itching, burning, irritation, dyspareunia, burning with urination, and a white, thick discharge.
  – Odor is uncommon.

• **Trichomoniasis**
  – Symptomatic patients will complain of abnormal discharge, itching, burning, or postcoital bleeding.

**PHYSICAL EXAM**

• **BV**
  – Thin, watery, sometimes foamy discharge. Can appear beige- or tan-colored. An amine or fishy smell may be present on exam.
  – The vaginal epithelium should appear normal and noninflamed.

• **VVC**
  – Erythema and swelling of the vulva and vaginal mucosa
  – Some patients may have vulvar excoriation and fissures.
  – If discharge is present, it is usually white, thick, and can have a cottage cheese appearance.
    Some women may have thin white diluted discharge. No odor is present.

• **DIV**
  – Purulent discharge
  – Wet mount shows white blood cells and parabasal (immature) squamous epithelial cells with pH >4.5.

• **Trichomoniasis**
  – Significant erythema of the vulva and vaginal mucosa
  – Greenish discharge with an amine or fishy odor
  – Discharge can also appear purulent in some patients.
  – Occasionally punctate hemorrhages can be seen on the vaginal walls and on the cervix ("strawberry cervix").

**DIFFERENTIAL DIAGNOSIS**

• Physiologic discharge
• Leukorrhea of pregnancy
• STDs
• Foreign body
• Contact dermatitis
• Cervicitis
• DIV
• Urinary tract infection (UTI)
• Atrophic vaginitis
• Dermatoses: lichen sclerosus, lichen planus, seborrheic dermatitis, psoriasis
DIAGNOSTIC TESTS & INTERPRETATION

- **BV**
  - Symptomatic patients complain of an abnormal vaginal discharge and a fishy odor.
  - Clinical diagnosis is established with Amsel criteria. A positive diagnosis can be made if 3 of 4 of the following criteria are present.
    - Thin, homogenous discharge
    - Vaginal pH >4.5
    - A positive amine or whiff test with use of KOH solution added to discharge
    - >20% of the epithelial cells identified as “clue cells”

- **VVC**
  - Visualization of blastospores or pseudohyphae on saline or 10% KOH microscopy
  - A positive culture in a symptomatic patient

- **Trichomoniasis**
  - Visualization of motile trichomonads on saline microscopy
  - Several POC identification tests, including patient performed, are available with increased sensitivity compared to microscopy but are expensive.

TREATMENT

GENERAL MEASURES

- Avoid douching and tight-fitting clothing.
- Regular use of condoms may help to prevent BV.
- Asymptomatic, pregnant women generally do not require treatment for BV.

MEDICATION

Medication recommendations based on Centers for Disease Control treatment guidelines (2)[A]

- **BV**
  - Metronidazole 500 mg orally BID for 7 days, 0.75% gel 1 applicator vaginally daily for 5 days, or clindamycin given vaginally (1 applicator = 100 mg) for 5 days. Recurrent infection may require repeated treatment (e.g., 1 week monthly for 6 months). Advise patients to avoid alcohol during treatment with oral metronidazole and for 3 days following.

- **VVC**
  - Uncomplicated infections can be treated with a one-time dose of fluconazole 150 mg tab. Topical/vaginal suppository antifungal regimens such as butoconazole, clotrimazole, miconazole, terconazole, or nystatin creams. Treatment can range from 3 to 7 days.
  - Recurrent or complicated infections may require additional oral dosing of fluconazole 150 mg tab for extended treatment and/or prophylaxis.
  - Non-albican candidiasis may require longer duration of treatment with topical or oral azoles.
  - Avoid oral azoles in pregnant women.
  - Advise patients that topical medications may weaken rubber or latex condoms.

- **Trichomoniasis**
  - A one-time 2-g oral dose of either tinidazole or metronidazole; alternatively, 500-mg dose of metronidazole BID for 7 days
  - The patient’s partner should be treated as well and counseled to abstain from sex until both patients have completed treatment and are asymptomatic.
– Test of cure is not necessary.
  ● DIV
    – Address estrogen deficiency
    – Clindamycin cream vaginally or
    – Hydrocortisone vaginal suppository 300 to 500 mg nightly for 3 weeks; may need additional maintenance

ISSUES FOR REFERRAL
Treating male partners does not reduce symptoms or prevent recurrence but can be considered in patients with recurrent infection.

COMPLEMENTARY & ALTERNATIVE MEDICINE
A Cochrane analysis reviewed the use of probiotics for BV and found inconclusive evidence to recommend probiotics as primary treatment or as a preventive strategy (3)[A]. Further study was recommended.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
  ● Delay sexual relations until symptoms clear/discomfort resolves.
  ● Use of condoms may reduce recurrence of BV.
  ● Consider suppressive therapy for recurrent infection.
  ● Monthly presumptive treatment may help reduce colonization of bacteria associated with BV (4)[C].

Patient Monitoring
No specific follow-up needed; if symptoms persist or recur within 2 months, repeat pelvic exam and culture.

PATIENT EDUCATION
American College of Obstetricians and Gynecologists (ACOG), 409 12th St. SW, Washington, DC 20024-2188; 800-762-ACOG: www.acog.org

PROGNOSIS
VVC: 80–90% of uncomplicated cases cured with appropriate treatment; 30–50% of recurrent infections return after discontinuation of maintenance therapy; there is a relatively high spontaneous remission rate of untreated symptoms as well.

COMPLICATIONS
  ● VVC may occur following treatment of BV.
  ● BV has been associated with an increased risk of acquisition and transmission of HIV.
  ● BV has been associated with increased risk of preterm birth, chorioamnionitis, postpartum and postabortal endometritis, and pelvic inflammatory disease.

Algorithm: Discharge, Vaginal

CODES

ICD10

- N76.0 Acute vaginitis
- B37.3 Candidiasis of vulva and vagina
- N95.2 Postmenopausal atrophic vaginitis

CLINICAL PEARLS

Clinical symptoms, signs, and microscopy have relatively poor performance compared with so-called gold standards such as culture and DNA probe assays, but these more sensitive assays can detect organisms that may not be causing symptoms.

- Most women experience relief of symptoms with therapy chosen without such gold standard tests, even when the treatment does not correspond with the underlying infection.
- Vaginal pH is underused as a diagnostic tool for evaluation of vaginitis.
VARICOSE VEINS
Natalie T. Dal’Bo, MD, BSc, Jana E. Montgomery, MD, ScM

BASICS

DESCRIPTION
- Superficial venous disease causing a permanent dilatation, elongation, and tortuosity of superficial veins ≥3 mm in diameter usually occurring in the legs and feet; caused by systemic weakness in the vein wall and may result from congenitally incomplete valves or valves that have become incompetent
- Affects legs where reverse flow occurs when dependent
- Truncal varices involve the great and small saphenous veins; branch varicosities involve the saphenous vein tributaries.
- Categorized as the following and using the clinical, etiologic, anatomic, and pathologic (CEAP) classification:
  - Uncomplicated (cosmetic): corresponds to CEAP 0,1, and 2
  - With local symptoms (pain confined to the varices, not diffuse): corresponds to CEAP 2
  - With local complications (superficial thrombophlebitis, may rupture causing bleeding): corresponds to CEAP 2, 3, 4
  - Complex varicose disease (diffuse limb pain, swelling, skin changes/ulcer): corresponds to CEAP 4, 5, 6
- System(s) affected: cardiovascular; skin

ALERT
Ulceration of varicose veins has a high rate of infection, which can lead to sepsis.

Geriatric Considerations
- Common; usually valvular degeneration but may be secondary to chronic venous insufficiency
- Elastic support hose and frequent rests with legs elevated rather than ligation and stripping

Pregnancy Considerations
- Frequent problem
- Elastic stockings are recommended for those with a history of varicosities or if prolonged standing is involved.

EPIDEMIOLOGY

Incidence
- Predominant age: middle age
- Predominant gender: female > male (2:1)

Prevalence
- Chronic vein abnormalities are present in approximately 50% of people; varicose veins are present in 10–30% of people
- It is estimated that ~6 to 7 million Americans have chronic venous insufficiency
- Prevalence of chronic venous disease varies among different populations (non-Hispanic Caucasians have more venous disease than African Americans, Asians, and Hispanics
ETIOLOGY AND PATHOPHYSIOLOGY

- Varicose veins are caused by venous insufficiency from faulty valves in ≥1 perforator veins in the lower leg, causing secondary incompetence at the saphenofemoral junction (valvular reflux).
- Valvular dysfunction causing venous reflux and subsequently venous hypertension (HTN)
- Failed valves allow blood to flow in the reverse direction (away from the heart), from deep to superficial and from proximal to distal veins.
- Deep thrombophlebitis
- Increased venous pressure from any cause (e.g., pregnancy, obesity)
- Congenital valvular incompetence
- Trauma (consider arteriovenous fistula; listen for bruit)
- Presumed to be due to a loss in vein wall elasticity with failure of the valve leaflets
- An increase in venous filling pressure is sufficient to promote varicose remodeling of veins by augmenting wall stress and activating venous endothelial and smooth muscle cells.
- Calf muscle pump failure
- Obstruction (proximal)
- Deep venous insufficiency can lead to secondary superficial varicosities via enlarging collaterals

Genetics
No gene has been identified; however, there does appear to be some inherited component.

RISK FACTORS
- Increasing age
- Family history
- Pregnancy, especially multiple pregnancies
- Prolonged standing
- Obesity
- Sedentary lifestyle
- History of phlebitis or prior thrombosis
- Lower extremity trauma
- Ligament laxity
- Female sex
- Smoking
- Congenital valvular dysfunction

GENERAL PREVENTION
- Maintain a healthy body mass index
- Regular exercise
- Avoid sitting or standing for prolonged periods of time
- Avoid smoking
- Wear compression stockings

COMMONLY ASSOCIATED CONDITIONS
- Stasis dermatitis
- Lipodermatosclerosis
- Venous ulceration (usually near medial malleolus/gaiter area
DIAGNOSIS

HISTORY
- Symptoms range from minor annoyance/cosmetic problem to a lifestyle-limiting problem.
- Localized symptoms: pain, burning, itching
- Generalized symptoms
  - Leg muscular cramp, aching
  - Leg fatigue, swelling, heaviness
- Symptoms often worse at the end of the day, especially after prolonged standing.
- Women are more prone to symptoms due to hormonal influences: worse during menses.
- No direct correlation with the severity of varicose veins and the severity of symptoms

PHYSICAL EXAM
Assess for sequelae of chronic venous disease and evaluate for etiologies including secondary causes.
- Inspection
  - Inspect lower extremities while the patient is standing. Varicose veins in the proximal femoral ring and distal portion of the legs may not be visible when the patient is supine.
  - Scars indicating prior surgery and/or trauma
  - Varicose veins are the following:
    - Dilated, tortuous superficial veins, ≥3 mm in diameter
    - Dark purple/blue in color, raised above the surface of the skin
    - Often twisted, bulging, and can look like cords
    - Most commonly found on the posterior/medial lower extremity
  - Telangiectasias ("spider veins")
    - Small, dilated blood vessel (arteriole, venule, or capillary)
  - Skin changes may include the following:
    - Eczema
    - Hemosiderosis
    - Atrophie blanche
    - Lipodermatosclerosis
    - Ulcers, most often above the medial malleolus
  - Edema of the affected limb may be present.
- Palpation
  - Palpate saphenofemoral junction (~4 cm inferolateral to pubic tubercle)
    - Assess for any saphena varix
    - Ask patient to cough; feel for any thrills or dilations at the junction
- Percussion
  - Perform the tap test on any obvious varicosities:
    - Place one hand on saphenofemoral junction and second hand on a varicose vein
    - Tap the saphenofemoral junction and feel for any reflux with second hand (indicating retrograde flow in vein)
    - Continue this with second hand moving distally down varicosity until reflux is no longer felt
- Special tests
  - Trendelenburg test
With the patient supine, raise one leg to allow venous blood to drain out
- One drained, place a tourniquet around the elevated leg, and then ask the patient to stand
  - If varicose veins do not reappear distal to tourniquet site, then the defect is proximal to the level of the tourniquet (i.e., the saphenofemoral junction)
  - If varicose veins reappear, this means the defect is below the level of the tourniquet.
    - In this case, continue to repeat the test with the tourniquet at a more distal site until the level of the defect can be identified (i.e., until varicose veins do not reappear with standing).
- Perthes test
  - Assesses patency of deep system
    - With patient supine, place tourniquet around upper thigh to occlude superficial veins
    - Ask patient to stand and either raise their heels off the ground quickly multiple times, or walk for 5 minutes
      - If the varicose veins disappear, this indicates that the deep venous system is competent.
      - If varicosities persist, this may indicate deep venous incompetence (this may be painful; warn the patient).
- Completion
  - Doppler ultrasound to assess for venous incompetence and deep venous system patency
  - Perform peripheral arterial exam, including ankle-brachial index
  - Peripheral nervous system exam, including sensory and motor

**DIFFERENTIAL DIAGNOSIS**

- For lower extremity pain:
  - Nerve root compression
  - Arthritis
  - Peripheral neuritis
  - Deep vein thrombosis
  - Superficial thrombophlebitis
  - Ischemia
  - Trauma

- For lower extremity ulcers:
  - Venous insufficiency
  - Arterial insufficiency
  - Neuropathy
  - Infectious
  - Trauma
  - Vasculitides
  - Drugs (e.g., warfarin skin necrosis, heparin-induced thrombocytopenia)
  - Inflammatory disorders (e.g., pyoderma gangrenosum, panniculitis)

- For lower extremity edema:
  - Bilateral:
    - Heart failure
    - Liver failure
    - Renal failure
    - Venous insufficiency
    - Lymphedema
    - Protein-calorie malnutrition
Medications (e.g., calcium channel blockers)
- Thyroid myxedema
- Trauma
- Proximal obstruction
- Lipedema
  - Unilateral:
    - Deep vein thrombosis
    - Trauma
    - Cellulitis
    - Lymphatic obstruction

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- No laboratory testing required specifically for varicose veins; any lab tests ordered would be performed to rule out other diseases on the differential, as above (e.g., D-dimer for deep venous thrombosis, brain natriuretic peptide for heart failure, liver function tests for liver failure, etc.)
- Duplex ultrasound: noninvasive imaging duplex ultrasound will confirm the etiology, anatomy, and pathophysiology of segmental venous reflux. The severity of both symptoms and signs tends to correlate with the degree of venous reflux, which is identified by duplex ultrasound as retrograde or reversed flow of >0.5 seconds duration in the superficial veins and >1 second in the deep system.
- CTV/MRV: primarily for imaging proximal veins

**Diagnostic Procedures/Other**
Duplex scanning, venous Doppler study, photoplethysmography, light-reflection rheography, air plethysmography, and other vascular testing should be reserved for patients who have venous symptoms and/or large (>4 mm in diameter) vessels or large numbers of spider telangiectasia indicating venous hypertension.

**Test Interpretation**
The CEAP classification is considered the gold standard of classification of chronic venous disorders. Clinical classification illustrating the current physical state is useful in clinical practice.
- 0: no visible or palpable signs of venous disease
- 1: spider veins or telangiectasias
- 2: varicose veins
- 3: edema
- 4: skin changes (pigmentation, eczema, lipodermatosclerosis, atrophie blanche)
- 5: healed ulcer
- 6: active ulcer

**TREATMENT**
- Indications for treatment include pain, aching, heaviness, fatigue, burning, edema, stasis dermatitis, recurrent superficial phlebitis, or ulceration.
- Conservative therapy (e.g., elevation, external compression, weight loss, exercise) as being
helpful.

- Compression stockings improve subjective symptoms, but have no real effect on progression or recurrence (1)[A]; significant failure rate due to nonadherence;
  - Typical compression levels:
    - 20 to 30 mm Hg: uncomplicated varicose veins for pain and edema control
    - 30 to 40 mm Hg: venous stasis ulcers
- The most important part of the stocking is the elastic below the knee, where the standing venous pressure is the highest.
- Sclerotherapy: indicated for telangiectasias and small varicose veins
  - Injection of sclerosant into a vein and then apply compression resulting in occlusive fibrosis without clot formation; chemical irritants (chromated glycerin), osmotic (hypertonic saline), detergent (sodium tetradecyl sulfate [STS] and polidocanol [POL])
  - Poor long-term results with liquid sclerotherapy (LS), however, foam sclerotherapy (FS) is an option for treatment of the incompetent saphenous vein. Ultrasound-guided FS is recommended as a second-line treatment.
- Thermal or radiofrequency (RFA) ablation:
  - RFA thermal energy (85–120°C) is used to seal the incompetent vein via heat damage. Endovenous laser ablation (EVLA) uses laser and fiber-optic catheter technology to generate thermal energy (up to 800°C).
  - RFA and EVLA have been demonstrated to be superior to open surgical techniques for the treatment of varicose veins with similar improvement in quality of life. NICE recommends using them as first-line treatment of truncal vein incompetence.
  - RFA has overall lower complication risk (2)[A].
- Surgical excision, vein ligation/stripping
- CHIVA/stab phlebectomy: Less-invasive approach based on venous hemodynamics with deliberate preservation of the superficial venous system. Reduces recurrence of varicose veins and produces fewer side effects than vein stripping.
- Nonthermal, nontumescent ablation: Mechanochemical endovenous ablation (MOCA) is a hybrid system composed of a rotating tip with simultaneous injection of liquid sclerosant and does not use heat energy.
- Low-dose diuretics only minimally effective.
- Stasis dermatitis can respond to a short course of topical steroids.

MEDICATION
There are no medications to treat varicose veins.

ISSUES FOR REFERRAL
NICE recommends referral of patients with:
- Symptomatic primary (or recurrent) varicose veins
- Skin changes
- Superficial venous thrombosis
- Venous leg ulcers
- Healed ulcers

ADDITIONAL THERAPIES
- Wear compression stockings while awake.
- Activity
– Frequent rest periods with legs elevated
– If standing is necessary, shift weight from side to side.
– Appropriate exercise
– Walking regimen after sclerotherapy
– Never sit with legs hanging down.
• Physical therapy
• Weight loss

SURGERY/OTHER PROCEDURES
Minimally invasive outpatient procedures are preferred.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
• Compression stockings or sequential compression
• Encourage patient ambulation as appropriate.
• Venous thromboembolism (VTE) prevention

ONGOING CARE

DIET
Weight-loss diet if obesity is a problem.

PATIENT EDUCATION
• Avoid long periods of standing and crossing legs.
• Exercise (walking, running) regularly to improve leg strength and circulation.
• Maintain a healthy weight for height.
• Wear elastic support stockings.
• Avoid clothing that constricts legs.

PROGNOSIS
Usual course: chronic

COMPLICATIONS
• Chronic edema
• Petechial hemorrhages
• Venous stasis dermatitis
• Pigmentation, inflammation (lipodermatosclerosis)
• Venous ulcers, +/- superimposed infection
• Complications with sclerotherapy include hyperpigmentation, matting, local urticaria, cutaneous necrosis, microthrombi, nerve damage, and allergic reactions
• Recurrence after surgical treatment
• Scarring/nerve damage from stripping technique

REFERENCES

**CODES**

**ICD10**
- I83.90 Asymptomatic varicose veins of unspecified lower extremity
- I83.009 Varicose veins of unsp lower extremity w ulcer of unsp site
- I83.10 Varicose veins of unsp lower extremity with inflammation

**CLINICAL PEARLS**
- Minimally invasive procedures are preferred.
- RFA and EVLA have been demonstrated to be superior to open surgical techniques for the treatment of varicose veins with similar improvement in quality of life. NICE recommends using them as first-line treatment of truncal vein incompetence.
VASCULITIS
Irene J. Tan, MD, FACR

BASICS

DESCRIPTION
An inflammatory disorder of blood vessels
- Clinical features result from the destruction of blood vessel walls with subsequent thrombosis, ischemia, bleeding, and/or aneurysm formation.
- Vasculitis is a large, heterogeneous group of diseases classified by the predominant size, type, and location of involved blood vessels.
  - Small-vessel vasculitis
    o Microscopic polyangiitis (MPA)
    o Granulomatosis with polyangiitis (GPA; formerly Wegener granulomatosis)
    o Eosinophilic granulomatosis with polyangiitis (EGPA; formerly Churg-Strauss syndrome)
    o Antiglomerular basement membrane disease (anti-GBM)
    o Cryoglobulinemic vasculitis
    o IgA vasculitis (formerly Henoch-Schönlein purpura)
    o Hypocomplementemic urticarial vasculitis
  - Medium-vessel vasculitis
    o Polyarteritis nodosa (PAN)
    o Kawasaki disease (KD)
  - Large-vessel vasculitis
    o Takayasu arteritis (TAK)
    o Giant cell arteritis (GCA)
- Vasculitis occurs as a primary disorder or secondary to infection, a drug reaction, malignancy, or connective tissue disease.
  - Variable vessel vasculitis
    o Behçet disease
    o Cogan syndrome
  - Single-organ vasculitis
    o Cutaneous leukocytoclastic angiitis
    o Cutaneous arteritis
    o Primary CNS vasculitis
  - Vasculitis associated with systemic disease
    o Lupus vasculitis
    o Rheumatoid vasculitis
    o Sarcoid vasculitis
  - Vasculitis associated with other etiology
    o Hepatitis C–associated cryoglobulinemic vasculitis
    o Hepatitis B–associated vasculitis
    o Syphilis-associated aortitis
    o Drug-induced immune complex vasculitis
    o Drug-associated antineutrophil cytoplasmic antibodies (ANCA)-associated vasculitis
    o Cancer-associated vasculitis
Protean features often delay definitive diagnosis.

**EPIDEMIOLOGY**

Highly variable, depending on the particular syndrome
- Hypersensitivity vasculitis is most commonly encountered in clinical practice.
- KD, IgA vasculitis, and dermatomyositis are more common in children.
- TAK is most prevalent in young Asian women. GPA, MPA, and EGPA are more common in middle-age males.
- GCA occurs exclusively in those >50 years of age and is rare in the African American population.

**Incidence**

Annual incidence in adults (unless otherwise specified)
- IgA vasculitis: 200 to 700/1 million in children <17 years of age
- GCA: 100 to 170/1 million in Caucasians age >50 years
- KD: depends on race/age; ~200/1 million
- PAN: 2 to 33/1 million
- GPA: 4 to 15/1 million
- MPA: 1 to 24/1 million
- EGPA: 1 to 3/1 million
- TAK: 2/1 million
- Primary CNS vasculitis: 2/1 million in adults
- Hypersensitivity vasculitis: depends on drug exposure
- Viral-/retroviral-associated vasculitis: unknown; >90% of cases of cryoglobulinemic vasculitis are associated with hepatitis C.
- Connective tissue disorder–associated vasculitis: variable

**ETIOLOGY AND PATHOPHYSIOLOGY**

- Three major immunopathogenic mechanisms
  - Immune-complex formation: systemic lupus erythematosus (SLE), IgA vasculitis (HSP), and cryoglobulinemic vasculitis
  - ANCA s: GPA, MPA, and EGPA
  - Pathogenic T-lymphocyte response: GCA and TAK
- Pathophysiology best understood where known drug triggers have been identified (e.g., antibiotics, sulfonamides, hydralazine)

**Genetics**

- Several vasculitides linked to candidate genes
- Mutation in CECR1 encoding adenosine deaminase 2 is associated with PAN.
- Angiotensin converting enzyme insertion/deletion polymorphis is associated with susceptibility to vasculitis, especially in Behçet disease and IgA vasculitis.

**RISK FACTORS**

A combination of genetic susceptibility and environmental exposure likely triggers onset.

**GENERAL PREVENTION**

Early identification is the key to prevent irreversible organ damage in severe forms of systemic vasculitis.
COMMONLY ASSOCIATED CONDITIONS
Hepatitis C (cryoglobulinemic vasculitis), hepatitis B (PAN), cytomegalovirus (CMV), Epstein-Barr virus (EBV), HIV (viral-/retroviral-associated vasculitis), SLE, rheumatoid arthritis (RA), Sjögren syndrome, mixed connective tissue disease (MCTD), dermatomyositis, ankylosing spondylitis, Behçet disease, relapsing polychondritis (CTD-associated vasculitis), respiratory tract methicillin-resistant Staphylococcus aureus (MRSA) in GPA, levamisole-adulterated cocaine, medications: propylthiouracil, methimazole, hydralazine, minocycline, levamisole-tainted cocaine

DIAGNOSIS

HISTORY
- Consider age, gender, and ethnicity.
- Comprehensive medication history
- Family history of vasculitis
- Constitutional symptoms: fever, weight loss, malaise, fatigue, diminished appetite, sweats
- CNS/PNS: mononeuritis multiplex, polyneuropathy, headaches, visual loss, tinnitus, stroke, seizure, encephalopathy
- Heart/lung: myocardial infarction, cardiomyopathy, pericarditis, cough, chest pain, hemoptyis, dyspnea
- Renal: hematuria
- GI: abdominal pain, hematochezia, perforation
- Musculoskeletal: arthralgia, myalgia
- Miscellaneous: unexplained ischemic or hemorrhagic events, chronic sinusitis, and recurrent epistaxis
- Note the organs affected and estimate the size of blood vessels involved.
- Demographics, clinical features, and the predominant vessel size/organ involvement help identify specific type of vasculitis.

PHYSICAL EXAM
- Vital signs: blood pressure (hypertension) and pulse (regularity and rate)
- Skin: palpable purpura, livedo reticularis, nodules, ulcers, gangrene, nail bed capillary changes
- Neurologic: cranial nerve exam, sensorimotor exam
- Ocular exam: visual fields, scleritis, episcleritis
- Cardiopulmonary exam: rubs, murmurs, arrhythmias
- Abdominal exam: tenderness, organomegaly

DIFFERENTIAL DIAGNOSIS
- Fibromuscular dysplasia
- Embolic disease (atheroma, cholesterol emboli, atrial myxoma, mycotic aneurysm with embolization)
- Drug-induced vasospasm (cocaine, amphetamines, ergots)
- Thrombotic thrombocytopenic disorders (disseminated intravascular coagulation [DIC], thrombotic thrombocytopenic purpura [TTP], antiphospholipid syndrome, heparin- or warfarin-induced thrombosis), thromboangitis obliterans
- Systemic infection (infective endocarditis, fungal infections, disseminated gonococcal
infection, Lyme disease, syphilis, Rocky Mountain spotted fever [RMSF], bacteremia, ehrlichiosis, babesiosis)

- Malignancy (lymphomatoid granulomatosis, angioimmunoblastic T-cell lymphoma, intravascular lymphoma)
- Miscellaneous (Goodpasture syndrome, sarcoidosis, amyloidosis, Whipple disease, congenital coarctation of aorta)

**DIAGNOSTIC TESTS & INTERPRETATION**

**ALERT**
Renal involvement is often clinically silent. Routine serum creatinine and urinalysis with microscopy are needed to identify underlying glomerulonephritis.

- Initial tests exclude alternate diagnoses and guide therapy.
- Routine tests
  - CBC
  - Liver enzymes
  - Serum creatinine
  - Urinalysis with microscopy
- Specific serology
  - Antinuclear antibodies (ANA)
  - Rheumatoid factor (RF)
  - Rapid plasma reagin/venereal disease reaction level (RPR/VDRL)
  - RMSF titers; Lyme titers
  - Complement levels C3, C4
  - ANCA
  - Antiproteinase 3 (anti-PR3) antibodies
  - Antimyeloperoxidase (anti-MPO) antibodies
  - Hepatitis screen for B and C
  - Cryoglobulin
  - Anti-GBM titer
  - HIV
  - Serum and urine protein electrophoresis
- Miscellaneous
  - Drug screen
  - ESR
  - C-reactive protein
  - Creatine kinase (CK)
  - Blood culture
  - ECG
- CXR, CT scan, MRI, and arteriography may be required to delineate extent of organs involved.

**Diagnostic Procedures/Other**

- Electromyography with nerve conduction can document neuropathy and target nerve for biopsy.
- Biopsy of affected site confirms diagnosis (e.g., temporal artery, sural nerve, renal biopsy).
- If biopsy is not practical, angiography may be diagnostic for large- and medium-vessel vasculitides.
Bronchoscopy may be required to differentiate pulmonary infection from potentially life-threatening hemorrhagic vasculitis in patients with hemoptysis.

**Test Interpretation**
Blood vessel biopsy shows immune cell infiltration into vessel wall layers with varying degrees of necrosis and granuloma formation, depending on the type.

---

**TREATMENT**

**GENERAL MEASURES**
- Discontinue offending drug (hypersensitivity vasculitis).
- Simple observation for mild cases of pediatric IgA vasculitis
- ANCA-associated vasculitis has two-phase treatment: initial induction followed by maintenance (steady tapering of corticosteroids with immunosuppressants or immunomodulators).

**MEDICATION**

**First Line**
Corticosteroids are initial anti-inflammatory of choice.

**Second Line**
Cytotoxic medications, immunomodulatory, or biologic agents (e.g., cyclophosphamide (1)[B], (2)[A], methotrexate (3)[A], azathioprine (3)[A], leflunomide (3)[A], mycophenolate mofetil (1)[B], and rituximab (2)[A]) are often required in combination with corticosteroids for rapidly progressive vasculitis with significant organ involvement or inadequate response to corticosteroids. Rituximab (2)[A] is the first FDA-approved treatment for GPA and MPA. Tocilizumab (4)[A] is the first FDA-approved treatment for GCA. Mepolizumab (5)[A] is the first FDA-approved treatment for EGPA.

**ISSUES FOR REFERRAL**
- Rheumatology referral for complicated cases where newer or more toxic treatments are required
- Nephrology referral for persistent hematuria or proteinuria, rising creatinine, or a positive ANCA titer
- Pulmonary referral for persistent pulmonary infiltrate unresponsive to antibiotic therapy or if gross hemoptysis

**ADDITIONAL THERAPIES**
- IVIG and aspirin for KD, where corticosteroids are contraindicated
- Plasma exchange appears to improve recovery of patients with severe acute renal failure secondary to vasculitis and pulmonary hemorrhage (3)[A].

**SURGERY/OTHER PROCEDURES**
Rarely, corrective surgery is required to repair tissue damage as a result of aggressive vasculitis.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Hemoptysis, acute renal failure, intestinal ischemia, any organ-threatening symptoms or signs, and/or need for biopsy
● Initial therapy is guided by the organ system involved.
  – If pulmonary hemorrhage is present, life-saving measures may include mechanical ventilation, plasmapheresis, and immunosuppression.
  – If acute renal failure is present, attend to electrolyte and fluid balance and consider plasma exchange and immunosuppression.
  – If signs of intestinal ischemia are present, make NPO and consider plasmapheresis, immunosuppression, and parenteral nutrition.
● Discharge criteria: stabilization or resolution of potential life-threatening symptoms

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
If significant coronary artery disease is involved in KD, moderate activity restriction may be of benefit.

Patient Monitoring
Frequent clinical follow-up supported by patient self-monitoring to identify disease relapse

DIET
Alter diets for patients with renal involvement or hyperglycemia/dyslipidemia.

PROGNOSIS
Prognosis is good for patients with vasculitis and limited organ involvement. Relapsing courses, renal, intestinal, or extensive lung involvement have a poorer prognosis.

COMPLICATIONS
● Persistent organ dysfunction may be the result of the disease, medications, or inflammation/scarring in the more serious forms of vasculitis.
● Early morbidity/mortality is due to active vasculitic disease; delayed morbidity/mortality may also be secondary to complications of chronic therapy with cytotoxic medications.

CODES

ICD10

- I77.6 Arteritis, unspecified
- M31.30 Wegener’s granulomatosis without renal involvement
- M30.0 Polyarteritis nodosa

CLINICAL PEARLS

- Suspect vasculitis in patients with a petechial rash, palpable purpura, glomerulonephritis, pulmonary-renal syndrome, intestinal ischemia, or mononeuritis multiplex.
- Exclude silent renal involvement by routinely obtaining serum creatinine and urinalysis with microscopy.
- Vasculitis has “skip” lesions, which may complicate diagnostic biopsy.
- In patients with vasculitis, look for an underlying inciting process such as medication, infection, thrombosis, or malignancy.
VENOUS INSUFFICIENCY ULCERS
Marcy Wiemers, MD ● Seena Mariate Jose, MD ● Hyunyoung Kim, MD, MPH

BASICS
- Venous insufficiency disorders include simple spider veins, varicose veins, and leg edema.
- In the United States, up to 35% of adults have chronic venous insufficiency.
- Venous leg ulcers are the most serious consequence of venous insufficiency.
- Venous leg ulcers are a type of chronic wound affecting up to 3% of adults in developed countries at some point during their lives.
- The annual estimated treatment cost of chronic venous ulcers is $2.5–3.5 billion per year.

DESCRIPTION
- Full-thickness shallow skin defect with surrounding pigmentation and well defined borders
- Most frequently located in ankle region of lower leg over bony prominences
- Present for >30 days and fails to heal spontaneously
- May only have mild pain unless infected
- Other signs of chronic venous insufficiency include bulging veins, edema, hyperpigmentation, dermatitis, woody fibrosis, lipodermatosclerosis.

EPIDEMIOLOGY
Up to 80% of leg ulcers are caused by venous disease; whereas arterial disease accounts for 10–25%, which may coexist with venous disease.

Incidence
- Overall incidence of venous ulcers is 18/100,000 persons.
- Prevalent sex: women > men (20.4 vs. 14.6/100,000 for venous ulcer); increased with age for both sexes

Prevalence
- Seen in ~1% of adult population in industrialized countries; increased to 4% in patients ≥80 years old
- Prevalence studies only available for Western countries
- Point prevalence underestimates the extent of the disease because ulcers often recur.
- 70% of ulcers recur within 5 years of closure.

ETIOLOGY AND PATHOPHYSIOLOGY
- In a diseased venous system, venous pressure in the deep system fails to fall with ambulation, causing venous hypertension.
- Venous hypertension comes from the following:
  - Venous obstruction
  - Incompetent venous valves in the deep or superficial system
  - Inadequate muscle contraction (e.g., arthritis, myopathies, neuropathies) so that the calf pump is ineffective
- Venous pressure transmitted to capillaries leading to venous hypertensive microangiopathy and
extravasation of red blood cells (RBCs) and proteins (especially fibrinogen)

- Increased RBC aggregation leads to reduced oxygen transport, slowed arteriolar circulation, and ischemia at the skin level, contributing to ulcers.
- Leukocytes aggregate to hypoxic areas and increase local inflammation.
- Factors promoting persistence of venous ulcers
  - Prolonged chronic inflammation
  - Bacterial infection, critical colonization

**Genetics**
Research suggests the presence of genetic influences in the pathology of venous disease, the profile of the genes involved remain poorly understood (FOXC2 is the first gene in which mutations are strongly associated with primary venous valve failure).

**RISK FACTORS**
- History of leg injury
- Age ≥55 years
- High body mass index (BMI)
- Congestive heart failure (CHF)
- History of deep venous thrombosis (DVT)
- Failure of calf muscle pump (e.g., ankle fusion, inactivity) is a strong independent predictor of poorly healing wounds.
- Previous varicose vein surgery or ulcers
- Family history

**GENERAL PREVENTION**
- Primary prevention after symptomatic DVT: Prescribe compression hose to be used as soon as feasible for at least 2 years (≥20 to 30 mm Hg compression).
- Secondary prevention of recurrent ulceration includes compression, correction of the underlying problem, and surveillance.
- Circumstantial evidence from two randomized controlled trials showed that in those who stopped wearing compression hose ulcers were more likely to recur.
- Avoiding lower leg trauma may help to prevent ulceration, as most ulcers develop from trauma.

**COMMONLY ASSOCIATED CONDITIONS**
Up to 50% of patients have allergic reactions to topical agents commonly used for treatment.
- Contact sensitivity was more common in patients with stasis dermatitis (62% vs. 38%).
- Avoid triple antibiotic ointment, including anything containing neomycin sulfate.

**DIAGNOSIS**
A diagnosis of venous reflux or obstruction must be established by an objective test beyond the routine clinical examination of the extremity.

**HISTORY**
- Family history of venous insufficiency and ulcers
- Recent trauma
- Nature of pain: achy (improved with leg elevation)
● Wound drainage
● Duration of wound and over-the-counter (OTC) treatments already attempted
● History of DVTs (especially factor V Leiden mutation; strongly associated with ulceration)
● History of leg edema that improves overnight (edema that does not improve overnight is more likely lymphedema)

PHYSICAL EXAM
● Look for evidence of venous insufficiency:
  – Pitting edema
  – Hemosiderin staining (red and brown diffuse pigment changes)
  – Stasis dermatitis
  – Atrophie blanche, ivory colored stellate scars
  – Lipodermatosclerosis (“bottle neck” narrowing in the lower leg from fibrosis and scarring)
● Look for evidence of significant lymphedema (i.e., dorsal foot or toe edema, edema that does not resolve overnight or with elevation). This may require referral for special comprehensive lymph therapy.
● Examine for palpable pulses.
● Examine wound for the following:
  – Length, width, depth to monitor wound healing rate
  – Presence of necrotic tissue
  – Presence of biofilms or infection: purulent material in the wound, increased amount odorous exudate, spreading cellulitis, fever, and chills
● Get initial and interim girth measurements (at ankle and midcalf) to monitor edema.
● Important to rule out poor arterial circulation:
  – Compression dressings cannot be used in patients with ankle-brachial index (ABI) <0.8.

DIFFERENTIAL DIAGNOSIS
● Arterial insufficiency ulcer
● Neuropathic ulcer
● Malignancy
● Sickle cell ulcer
● Vasculitic ulcer
● Calciphylaxis
● Cryoglobulinemia
● Pyoderma gangrenosum
● Collagen vascular disease
● Leishmaniasis
● Cutaneous tuberculosis

DIAGNOSTIC TESTS & INTERPRETATION
● Consider prothrombin time (PT)/international normalized ratio (INR) and partial thromboplastin time (PTT) if patient is anticoagulated.
● Consider biopsy of leg ulcers that fail to heal or have atypical features.
● Consider factor V Leiden mutation; strongly associated with venous ulcers
● Test for diabetes as necessary with fasting glucose.
● Use duplex imaging to diagnose anatomic and hemodynamic abnormalities with venous insufficiency. It will also identify any DVT present.
Diagnostic Procedures/Other
- Check ABI for evidence of arterial disease.
- Duplex imaging for evaluation of superficial and deep venous reflux and incompetent perforator veins
- With concomitant severe arterial insufficiency, refer to a vascular surgeon for revascularization.

Test Interpretation
Strongly consider biopsy on wounds with atypical locations, failure to heal, or any suspicion of malignancy.

TREATMENT
- Treatment options: conservative management, mechanical treatment, medications, and surgical options
- Goals: Reduce edema, improve ulcer healing, and prevent recurrence

GENERAL MEASURES
- Compression therapy is the standard of care for venous ulcers and chronic venous insufficiency (1)[C].
- Leg elevation: requires raising the legs above the level of the heart to reduce edema and improve microcirculation and oxygen delivery; is most effective if performed for 30 minutes, 3 to 4 times a day.
- Dressings are used under compression bandages to promote faster healing and prevent adherence of the bandage to the ulcer; types include: hydrocolloids, foams, hydrogels, paste, and simple nonadherent dressing.
- The choice of dressing can be guided by cost, ease of application, patient’s and physician’s preference.
- If exudative, use absorptive dressing (calcium alginate or absorptive pads) (1)[A]. If minimal exudate, use hydrocolloid. If wound tends to be dry, use hydrogel.
- To prevent maceration of surrounding skin, use a barrier ointment/cream.
- Conservative management
  - Compression therapy methods: inelastic, elastic, and intermittent pneumatic compression. Outcome: reduces edema, improves venous reflux, enhances healing of ulcers, and reduces pain (2)[C].
  - Success rates range from 30% to 60% at 24 weeks and 70–85% after 1 year.
  - After an ulcer has healed, lifelong maintenance of compression therapy may reduce the risk of recurrence.
  - Adherence to therapy may be limited by pain, drainage, application difficulty, and physical limitations (obesity and contact dermatitis).
  - Contraindications: clinically significant arterial disease (ABI <0.8) and uncompensated heart failure
  - Inelastic compression therapy: provides pressure during ambulation and muscle contraction but no resting pressure. Most common: Unna boot (zinc oxide moist bandage that hardens after application)
  - Elastic: sustain compression during rest and activity. Compression stockings: Pressure
should be at least 20 to 30 mm Hg and preferably 30 to 40 mm Hg. They should be removed at night and should be replaced every 6 months. Elastic bandages (i.e., Profore) are alternatives to compression stockings.

- Intermittent pneumatic compression is expensive and requires immobilization, therefore is generally reserved for bedridden patients.

- Mechanical treatment
  - Negative pressure wound therapy (NPWT) (i.e., vacuum-assisted closure [VAC] dressings) may be beneficial but no clear benefit has been shown.

**MEDICATION**

- Pentoxifylline 400 mg PO TID, GI side effects are common (nausea, vomiting, diarrhea, heartburn, loss of appetite) (3)[A].
- Aspirin 300 mg PO daily and statins may potentially have a benefit (3)[A].
- Routine use of antibiotics for all venous ulcers is not recommended (1)[A].

**ISSUES FOR REFERRAL**

- With prominent toe or foot edema, consider lymphedema. Refer to a certified lymphedema therapist (CLT).
- Refer to a wound clinic for complex, large or poorly healing ulcers (greater than 3 months or >10 cm).
- Refer to a vascular specialist for recurrent ulcers and/or ABI <0.8.
- Use home health nurses to help with immobile patients needing frequent wrapping/dressing changes.

**ADDITIONAL THERAPIES**

- Edema management: Reduce venous hypertension and improve venous return to reduce inflammation, pain, and improve healing.
- Encourage exercise (e.g., activation of calf muscle pump with ankle flexion and extension) in conjunction with leg compression and elevation.
- Infection control
  - Débridement of necrotic tissue
  - Treat cellulitis (usually gram-positive bacteria) with bactericidal systemic antibiotics. Suspect local infection when there is pain or no improvement in the wound after 2 weeks of compression. Consider deep quantitative swab, after thorough cleansing, or tissue biopsy for culture.
  - Treat critical colonization with topical antimicrobials, such as cadexomer iodine (silver dressings and honey are widely used, but definitive data are lacking) (1)[A].

**SURGERY/OTHER PROCEDURES**

- Current evidence does not definitively support the superiority of surgical interventions (open or endovascular) compared with compression alone with respect to ulcer healing, time to healing, and recurrence in patients with lower extremity venous ulcer disease (4).

- However, there is some evidence that early venous ablation and surgical intervention to correct venous reflux can decrease reoccurrence and improve healing in some patients (5)[B].
- If necrotic tissue, consider sharp débridement.
- Skin grafting generally is not effective if there is persistent edema, and the underlying venous disease is not addressed.
- Allografts made of synthetic bilayered skin with living keratinocytes and fibroblasts are the
only cellular tissue product (CTP) to improve healing at 6 months. There is insufficient evidence to support use of autografts, xenografts (3).

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Chestnut seed extract (50 mg BID) and flavonoids are effective for venous insufficiency but not ulceration.
- Topical medicinal honey used on wounds shows no evidence of improved healing.
- Oral zinc has not been shown to be beneficial.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Consider for those with acute significant cellulitis.
- Infected wounds in diabetic patients usually requires IV antibiotics.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- When ulcers are nearly healed and edema is controlled, switch from compression bandages to compression hose.
- Insurance may not reimburse for compression hose unless an ulcer is present. Consider referral for hose fitting prior to the ulcer being healed.

Patient Monitoring
Monitor the ulcer for healing by measuring its area. Expect at least 10% reduction every 2 weeks. Monitor for infection and rare malignant change.

DIET
- Low-salt diet is recommended for patients with fluid overload.
- Weight loss is recommended for patients with a high BMI.

PATIENT EDUCATION
- Patient education of underlying mechanism is important for long-term management.
- Long-term plan for edema management and use of compression therapy is essential.
- Wound care
- Early recognition and treatment of new ulcers or cellulitis

PROGNOSIS
- Venous insufficiency is a lifelong medical problem.
- Ulcers recur frequently. Early identification and immediate treatment are essential.
- Ongoing diligence with edema control, avoiding infections, and avoiding trauma are important.

COMPLICATIONS
Venous insufficiency ulcers significantly reduce health-related quality of life, especially in younger cohorts.

REFERENCES

ADDITIONAL READING

CODES

ICD10
- I87.2 Venous insufficiency (chronic) (peripheral)
- I83.009 Varicose veins of unsp lower extremity w ulcer of unsp site
- I89.0 Lymphedema, not elsewhere classified

CLINICAL PEARLS
- Venous stasis: dull ache or pain in lower extremities, swelling that subsides with elevation, changes of the surrounding skin, and varicose veins
- Venous ulcers often occur over bony prominences (medial malleolus) and are generally irregular and shallow. Granulation tissue and fibrin are often present in the ulcer base.
- The diagnosis of venous ulcers is clinical.
- Tests such as ABI and color duplex ultrasonography may be helpful if the diagnosis is unclear.
- Compression therapy is the standard of care for venous ulcers and chronic venous insufficiency, but may be contraindicated if ABI <0.8
- Clinical severity score can guide the assessment: CEAP (clinical, etiology, anatomy, and pathophysiology). Poor prognostic factors for venous ulcers include large size and prolonged duration.
- Treat critical colonization with topical antimicrobials (avoid neomycin).
- Refer patients with recurrent or venous ulcers failing to heal with moist wound care and compression after 4 to 6 weeks to wound specialist.
VENTRICULAR SEPTAL DEFECT
Luay Sarsam, MD ● Cherry Onaiwu, MD, MS

BASICS

DESCRIPTION
- Congenital (usually) or acquired defect in the interventricular septum that allows communication of blood between the left and the right ventricles
- Second most common congenital heart malformation reported in infants and children. It can also occur as a late complication of acute myocardial infarction (MI)
- Severity of the defect is correlated with its size, with large defects being the most severe
- Blood flow across the defect typically is left to right, depending on defect size and pulmonary vascular resistance (PVR)
- Prolonged left to right shunting of blood can lead to pulmonary hypertension (HTN). This may eventually lead to a reversal of flow across the defect and cyanosis (Eisenmenger complex)

Geriatric Considerations
Almost entirely associated with late complication of MI

Pediatric Considerations
Congenital defect

ALERT
- Pregnancy may exacerbate symptoms and signs of a ventricular septal defect (VSD).
- Can be tolerated during pregnancy if VSD is small
- May be associated with an increased risk of preeclampsia in women with an unrepaired VSD

EPIDEMIOLOGY

Incidence
- Congenital defect: no gender predilection, occurs in ~2/1,000 live births and accounts for 30% of all congenital cardiac malformations
- Post-MI: Some studies suggest that gender may play a role

Prevalence
In the United States:
- Occurs in ~50% of all children with congenital heart disease
- Low prevalence in adults (~0.3 per 1,000) due to spontaneous closure
- Post-MI complication in ~0.2–3% of cases

ETIOLOGY AND PATHOPHYSIOLOGY
- Congenital
- In adults, late complication of MI
- Some reports of iatrogenic causes

Genetics
Multifactorial etiology; autosomal dominant and recessive transmissions have been reported.
RISK FACTORS

- Congenital VSD:
  - Risk of sibling being affected: 4.2%
  - Risk of offspring being affected: 4%
  - Prematurity
- Post-MI VSD:
  - Advanced age
  - Arterial HTN
  - First MI
  - Most frequent within 1st week after MI
  - Most commonly after anterior wall acute MI

GENERAL PREVENTION

Avoid prenatal exposure to known risk factors (ibuprofen cyclooxygenase [COX] inhibitors, marijuana, organic solvents, febrile illness). For adults, avoid risk factors for MI and obtain evaluation before pregnancy.

COMMONLY ASSOCIATED CONDITIONS

- Congenital:
  - Tetralogy of Fallot
  - Aortic valvular deformities, especially aortic insufficiency and bicuspid aortic valve
  - Down syndrome (trisomy 21), endocardial cushion defect
  - Transposition of great arteries
  - Coarctation of aorta
  - Tricuspid atresia
  - Truncus arteriosus
  - Patent ductus arteriosus
  - Atrial septal defect
  - Pulmonic stenosis
  - Subaortic stenosis
- Adult: coronary artery disease

DIAGNOSIS

HISTORY

- Presentation depends on degree of shunting across the defect; may be completely asymptomatic with small defects
- Respiratory distress, tachypnea, tachycardia
- Diaphoresis with feeds, poor weight gain in infants

PHYSICAL EXAM

- Small defect:
  - Harsh holosystolic murmur loudest at left lower sternal border
  - Detected after PVR drops at 4 to 8 weeks of life
- Moderate defect:
  - Harsh holosystolic murmur at left lower sternal border associated with a thrill
– Forceful apical impulse with lateral displacement
– Increased intensity of \( P_2 \)
– Diastolic rumble at apex due to increased flow across the mitral valve

**Large defect:**
– Holosystolic murmur heard throughout the precordium with diastolic rumble at apex with precordial bulge and hyperactivity, although large defects may have little or no murmur initially
– If congestive heart failure (CHF) exists: tachycardia, tachypnea, and hepatomegaly
– If pulmonary HTN exists: cyanosis with exertion
– If severe, irreversible pulmonary HTN (Eisenmenger complex) exists: cyanosis, clubbing, syncope, arrhythmias, and polycythemia

**DIFFERENTIAL DIAGNOSIS**
- Patent ductus arteriosus, atrial septal defect
- Children: tetralogy of Fallot
- Adults: mitral regurgitation

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- A 12-lead electrocardiogram may show left ventricular hypertrophy and left atrial enlargement initially. As pulmonary HTN develops, right ventricular hypertrophy and right atrial enlargement may be seen.
- A chest x-ray (CXR) may demonstrate increased pulmonary vascularity and/or cardiomegaly.
- A 2D echocardiogram using color Doppler and bubble study for visualization of location, size of defect, and shunt direction
- Color flow Doppler for direction and velocity of VSD jet; may be used to estimate right ventricular pressure
- Ventriculography in conjunction with above imaging modalities can aid in characterization of VSD but is invasive

**Follow-Up Tests & Special Considerations**
- Weight and hematocrit check
- Serial echocardiograms
- Cardiac catheterization performed occasionally for perioperative planning or to assess need for closure of defect

**Diagnostic Procedures/Other**
- Cardiac catheterization (left and right sides of heart) can confirm the diagnosis, document number of defects, quantify ratio of pulmonary blood flow to systemic blood flow (Qp/Qs), and determine PVR.
- Demonstration of an oxygen saturation step up from the right atrium to the distal pulmonary artery

**Test Interpretation**
- Congenital VSD (four major anatomic types)
  - Membranous (70%)
  - Muscular (20%)
  - Atrioventricular canal type (5%)
– Supracristal (5%; higher in Asians)
- Post-MI VSD predominantly involves muscular septum.
- Right bundle branch block is common after surgical repair.

**TREATMENT**

- Small VSD tends to close spontaneously during childhood and has low risk for complications.
- Larger VSD tends to persist into adulthood and has more risk for complications.
- Start diuretic therapy if signs of fluid overload
- Minimize IV fluids.
- Consider angiotensin-converting enzyme inhibitor and/or digoxin.
- Nasogastric feeds for neonates
- Correct anemia via iron supplementation or a possible red blood cell transfusion.

**GENERAL MEASURES**

- Appropriate health care maintenance
- Outpatient, until surgical repair is indicated
- Inpatient management in setting of acute MI
- Inpatient for treatment of severe CHF

**MEDICATION**

**First Line**

</tbody>
</table>

**Second Line**

- Surgical closure is indicated if the pulmonic-to-systemic flow is >2:1 or with poorly controlled pulmonary overcirculation despite maximal medical and dietary interventions.
- If an infant with a VSD has persistent pulmonary HTN or failure to grow, surgical repair is
recommended prior to 6 months of age even if patient is otherwise asymptomatic.

- For post-MI VSDs, afterload reduction, inotropic support, intra-aortic balloon pump, and left ventricular assist device may be used to stabilize the patient prior to surgery. Surgical repair includes septal débridement and patch placement.

**ISSUES FOR REFERRAL**
Close follow-up of a congenital VSD is necessary until primary intracardiac repair is performed to ensure that significant pulmonary HTN does not develop.

**ADDITIONAL THERAPIES**
- Infant caloric requirements up to 150 kcal/kg/day or more for adequate weight gain
- Treatment of iron deficiency anemia to increase oxygen-carrying capacity

**SURGERY/OTHER PROCEDURES**
- Surgical correction with either a VSD patch or repair is commonly used. Postsurgical outcomes for isolated VSD are excellent. Complications are rare and include reoperation for residual VSD, extended hospital stay, arrhythmias, valve injury, depressed ventricular function, and heart block (2)[B]
- Percutaneous transcatheter device closure has become a safe and effective option for some children with small to moderate VSDs. Complications include valvular regurgitation, residual defects, and heart block. There is a greater risk of conduction abnormality with this technique compared to surgical closure. Recent studies have shown steroids may decrease this risk (3)[A]
- Perventricular device closure (hybrid technique) of some subtypes of isolated VSDs without cardiopulmonary bypass is feasible under transesophageal echocardiographic (TEE) guidance. Complications are similar to percutaneous closure (4)[A].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Failure to thrive
- Pulmonary overcirculation/CHF
- Stabilize airway
- Reduce temperature stress.
- Frequent vital sign monitoring; daily weight and calorie counts
- Discharge criteria: CHF stabilization, weight gain, or successful repair

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Small VSDs without evidence of CHF or pulmonary HTN generally can be followed every 1 to 5 years after the neonatal period
- Moderate to large VSDs require more frequent follow-up
- Potential complications of VSDs include right ventricular outflow obstruction and aortic valve prolapse

**Patient Monitoring**
- Physical growth and development monitoring
- Influenza vaccine for children >6 months of age
Palivizumab to children <12 months of age with hemodynamically significant lesions. Children with small VSDs do not need RSV prophylaxis (5)[A].

DIET
- Low sodium in heart failure
- High calorie in failure to thrive

PATIENT EDUCATION
- No activity restriction in absence of pulmonary HTN
- Parents need support and instructions for prevention of complications until the child is ready for surgery.

PROGNOSIS
- Congenital:
  - Course is variable depending on the size of the VSD
  - Small VSD: Many will close spontaneously by age 3 years. Muscular defects are more likely to close spontaneously.
  - Large VSD: CHF or failure to thrive in infancy necessitating surgical repair
  - 20-year cumulative survival rate after surgery for isolated VSD is 87%; 40 years is 78% (6)
  - Progressive pulmonary vascular disease and pulmonary HTN are the most feared complications of VSD caused by left-to-right shunting and may eventually lead to reversal of the shunt (Eisenmenger complex). Death usually occurs in the 4th decade of life if untreated.
- Post-MI:
  - With medical management alone, 80–90% mortality in the first 2 weeks
  - Prognosis worse with inferior MI compared with anterior MI

COMPLICATIONS
- CHF
- Aortic insufficiency
- Sudden death
- Hemoptysis
- Cerebral abscess
- Paradoxical emboli
- Cardiogenic shock
- Heart block rarely may accompany surgical closure
- Pulmonary HTN, particularly Eisenmenger complex

REFERENCES

### ADDITIONAL READING

### SEE ALSO

Acute Coronary Syndromes: NSTE-ACS (Unstable Angina and NSTEMI); Down Syndrome; Tetralogy of Fallot

### CODES

**ICD10**

- Q21.0 Ventricular septal defect
- I23.2 Ventricular septal defect as current comp following AMI
- Q21.3 Tetralogy of Fallot

### CLINICAL PEARLS

- A loud 2/6 to 3/6 low-pitched harsh holosystolic murmur at the left lower sternal border is typical.
- A diastolic rumble at the apex indicates moderate to large VSD or ratio of pulmonary to systemic blood flow (Qp/Qs) >2:1, which likely will require surgical or percutaneous closure.
- Disappearance of the murmur could be secondary to spontaneous closure of the defect or the development of pulmonary HTN.
- Development of a new murmur of semilunar valve insufficiency should be further evaluated. Pulmonary regurgitation may occur as PVR increases, and the development of aortic regurgitation usually will require early surgery.
BASICS

DESCRIPTION

- A symptom, not a disease process. Causes can be peripheral or central, benign, or life-threatening. Cause determines treatment.
- May be described as a sensation of movement (“room spinning”) when no movement is actually occurring.
- However, do not rely on symptom quality—often unreliable. Focus on timing and triggers.
- System(s) affected: nervous, cardiovascular, psych
- Synonym(s): dizziness

EPIDEMIOLOGY

Incidence

- Vertigo/dizziness accounts for >4 million ED visits a year in United States, of which 80–85% have no serious underlying condition (1).
- Predominant sex: female = male; women are 3 times more likely to experience vertiginous migraine (2).

Geriatric Considerations

- Keep a higher index of suspicion for CVD, arrhythmias, and orthostatic hypotension.
- Benign Paroxysmal Positional (BPPV) is more common in ages 50 to 70 years (2), an important risk factor for falls but is often undiagnosed.
- Medications are implicated almost 1/4 of the time (2).

Prevalence

- Ranges from 5% to 10% within the general population
- Lifetime prevalence for BPPV is 2.4%.

ETIOLOGY AND PATHOPHYSIOLOGY

- Dysfunction of the rotational velocity sensors of the inner ear results in asymmetric central processing; combination of sensory disturbance of motion and malfunction of the central vestibular apparatus.
- Peripheral causes: acute vestibular neuritis, BPPV (posterior canal 85–95%, lateral canal 5–15%), Ménière disease, otosclerosis, acute labyrinthitis, cholesteatoma, perilymphatic fistula, superior canal dehiscence syndrome, motion sickness (2). BPPV, vestibular neuritis, and Ménière disease account for majority of peripheral causes (2).
- Central causes: cerebellar tumor, stroke, migraine, vestibular ischemia (1,2)
- Drug causes: psychotropic agents, anticonvulsants, aspirin, aminoglycosides, furosemide (diuretics), amiodarone, α-/β-blockers, nitrates, urologic medications, muscle relaxants, phosphodiesterase inhibitors (sildenafil), excessive insulin, ethanol, quinine, cocaine
- Other causes: orthostasis, arrhythmia, psychological

Genetics
Family history of CVD/migraines may indicate higher risk of central causes.

**RISK FACTORS**
- History of migraines
- History of CVD/risk factors for CVD
- Use of ototoxic medications
- Trauma/barotrauma
- Perilymphatic fistula
- Heavy weight-bearing
- Psychosocial stress/depression
- Exposure to toxins

**GENERAL PREVENTION**
If due to motion sickness, consider pretreatment with anticholinergics, such as scopolamine.

**DIAGNOSIS**

**HISTORY**
- Focus on triggers and timing (2).
  - TiTrATE is a clinically useful evaluation tool: Timing, Triggers, And a Targeted Evaluation (1,2).
  - Timing: episodic or continuous. Episodic may last seconds to a few days. Continuous lasts days to weeks.
    - If continuous, assess for trauma or toxins (including prescribed and recreational).
    - To further evaluate continuous, spontaneous vertigo, perform HINTS exam (1,2,3) (see “Physical Exam”).
    - If episodic, assess for triggers.
  - Triggers: present or absent
    - If triggers, perform Dix-Hallpike maneuver (see “Physical Exam”).
    - Do not confuse worsening of symptoms with motion to be the same as triggering. Many central vertigos are worse with movement (1,2).
    - If no triggers, assess for hearing loss, migraines, or psych symptoms. Cardiovascular causes may also fall into this category.
  - And a Targeted Evaluation: See “Physical Exam” for more details.
- Specific history items that suggest a diagnosis:
  - Unilateral hearing loss suggests Ménière disease (2). Further assess to determine if sensorineural versus conductive because the latter suggests otosclerosis.
  - Symptoms triggered by sudden change in head position suggest BPPV.
  - Symptoms triggered when going from sitting to standing suggests orthostatic hypotension.
  - History of migraines suggests vestibular migraine. Differentiate from nonmigrainous headaches, which can also be present with CNS tumors.
  - Depressed mood/anxiety with episodic vertigo that has since become continuous suggests psychiatric causes.
  - History of unilateral sensory or motor symptoms indicates a central cause such as TIA or CVA until proven otherwise.
  - Onset after decompression (diving, flying) suggests decompression sickness or barotrauma.
PHYSICAL EXAM

- Cardiovascular: orthostatic blood pressure assessment on patients with episodic symptoms (1,2)
- HEENT: may identify barotrauma, otosclerosis, cholesteatoma. Also check Rinne and Weber tests if hearing loss.
- Neurologic: Assess for nystagmus in all patients (2).
  - Vertical nystagmus is almost always of central origin.
  - Nystagmus of peripheral origin may be horizontal or rotational.
- Dix-Hallpike maneuver: for episodic, triggered vertigo (2,4): Rapidly move the patient from a seated to supine position with the head turned 45 degrees to the right and held just over (below) the edge of the exam table. Observe for nystagmus and patient report of vertigo. Nystagmus/vertigo may not appear immediately. Wait until symptoms resolve and then return the patient to the sitting position. Repeat on the left.
  - The presence of extinguishing horizontal nystagmus is a positive test. If induced nystagmus does not subside, however, consider central causes and perform HINTS.
  - Vertical nystagmus always indicates a central cause even if triggered by Dix-Hallpike.
  - In primary care, PPV of 83% for BPPV and NPV of 52%
  - If Dix-Hallpike negative, check for lateral canal BPPV with a log roll test (4).
  - If duration and trigger of symptoms are not consistent with BPPV, do not perform Dix-Hallpike to avoid overlooking a central cause.
- HINTS exam: Perform for continuous, spontaneous vertigo with spontaneous nystagmus (1,2,3).
  - Horizontal Head Impulse: Rapidly and repeatedly bring patient’s head to midline from 20 degrees. Patients with vestibular neuritis will show rapid saccades to refocus on a target. With normal peripheral nervous function, eyes stay on target, raising concern for central causes.
  - Direction changing Nystagmus: Having already assessed for presence and direction of nystagmus, now check for changing direction. Nystagmus that changes direction with eye motion indicates a central lesion.
  - Test of Skew: Vertical eye movement during cover-uncover test indicates a central lesion. A normal test has no movement.
  - A combination of these findings is 96.8% sensitive and 98.5% specific for CVA/other central cause (HINTS positive) (3)[C].
  - If a patient meets criteria for HINTS exam, do not perform Dix-Hallpike.
- Perform a full neuro exam if diagnosis not already clear, paying attention to sensation, gait, and Romberg testing.

DIFFERENTIAL DIAGNOSIS

Causes (1,2):

- BPPV (episodic, triggered, positive Dix-Hallpike)
- Orthostatic hypotension (episodic, triggered, positive orthostatic blood pressure drop)
- Ménière disease (episodic, spontaneous, associated with unilateral sensorineural hearing loss)
- Otosclerosis (spontaneous, duration varies, unilateral conductive hearing loss)
- Vestibular migraine (episodic, associated with migraine HA)
- CVD (continuous, spontaneous; HINTS exam shows normal horizontal head impulse,
direction-changing nystagmus, or vertical skew on cover-uncover)
- Posterior fossa tumor (continuous, spontaneous)
- Psychiatric (associated psych symptoms)
- Medication/toxin (continuous, medication/substance history, evaluation otherwise negative)
- Other cardiovascular such as arrhythmia (episodic, often no triggers or triggered by exertion)
- Hypoglycemia (episodic, associated medications or comorbidities)
- Perilymphatic fistula, canal dehiscence (trauma including suspicion of barotrauma from history)
- Decompression sickness (acute, recent dive or flight)
- Degenerative neurologic disease (often progressive by history, associated neurologic findings)
- Peripheral neuropathy

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Labs not routinely necessary unless abnormal neuro exam, and identify a cause in <1% of patients (2)[C]
- Obtain MRI if a central cause is suspected to rule out stroke. CT cannot reliably see the posterior fossa and will not show changes in the early stages of an infarct. Vertigo may be the only symptom of acute stroke (3)[C].
- ENT/audiology referral if Ménière disease suspected for electronystagmography (2)[C]
- If acoustic neuroma is suspected, either CT or MRI to evaluate internal auditory canal (2)[C]

**Diagnostic Procedures/Other**

Audiometry if acoustic neuroma or Ménière disease is suspected

---

**GENERAL MEASURES**

Treatments depend on cause.

- **BPPV:** Epley maneuver and modified Epley maneuver (2)[A] (Epley maneuver–YouTube) (5)[B]
- **Vestibular neuritis and labyrinthitis**
  - Vestibular-suppressant medications (2)[C]
  - Vestibular rehabilitation exercises (2)[B]
  - No evidence to support improvement of symptoms with corticosteroid use (6)[B]
- **Ménière disease** (see separate topic) (2)[B]:
  - Low-salt diet (<1 to 2 g/day)
  - Diuretics such as hydrochlorothiazide
- **Vascular ischemia:** prevention of future events through blood pressure reduction, lipid lowering, smoking cessation, antiplatelet therapy, and anticoagulation, if necessary (2,3)[C]; MRI or CT if suspected
- **Vertiginous migraines:** dietary and lifestyle modifications, vestibular rehab, prophylactic and abortive medications (2)[C]
- **Psychological:** SSRIs are better than benzodiazepines for anxiety-related vertigo. Use slow titration to avoid worsening symptoms (7)[B].
MEDICATION
Avoid use of medication in mild cases. Use for a few days only because longer use may impair adaptation/compensation by the brain (2); medications not recommended for BPPV (4)[C]
- Meclizine: 12.5 to 50.0 mg PO q4–8h (2)
- Dimenhydrinate: 50 mg PO q6hr (2)
  - Precautions: prostatic hyperplasia, glaucoma
  - Adverse effects: sedation, xerostomia
  - Interactions: CNS depressants
- Prochlorperazine: 5 to 10 mg PO or IM q6–8h; 25 mg rectally q12h; 5 to 10 mg by slow IV over 2 minutes (2)
  - Contraindications: blood dyscrasias, age <2 years, hypotension
  - Precautions: acutely ill children, glaucoma, breast cancer history, impaired cardiac function, prostatic hyperplasia
  - Adverse effects: sedation, extrapyramidal effects
  - Interactions: phenothiazines, tricyclics antidepressants
- Metoclopramide: 5 to 10 mg PO q6h, 5 to 10 mg slow IV q6h (2)
  - Contraindications: concomitant use of drugs with extrapyramidal effects, seizure disorders
  - Precautions: history of depression, Parkinson disease, hypertension
  - Adverse effects: sedation, fluid retention, constipation
  - Interactions: linezolid, cyclosporine, digoxin, levodopa
- Psychiatric causes
  - SSRIs preferred for frequent vertigo related to depression/anxiety (6)[B]
  - Lorazepam (Ativan) 0.5 to 2.0 mg PO, IM, or IV q4–8h for short-term relief of more severe anxiety-related vertigo
  - Diazepam (Valium) 2 to 10 mg PO or IV q4–8h for short-term relief of more severe symptoms

Geriatric Considerations
Use vestibular-suppressant medications with caution due to increased risk of falls and urinary retention.

Pregnancy Considerations
Meclizine and dimenhydrinate are pregnancy Category B.

ISSUES FOR REFERRAL
Consider referral to otolaryngologist, ENT specialist, vestibular rehabilitation therapist, or neurologist if patient requires further care.

ADDITIONAL THERAPIES
- Epley maneuver/modified Epley maneuver for BPPV to displace calcium deposits in the semicircular canals (4)[A]
  - Effective for short-term symptomatic improvement and for converting patient from positive to negative Dix-Hallpike maneuver. Some studies suggest long-term relief (4)[C].
- Lateral canal BPPV may respond to barbecue roll maneuver (4)[C].
- Vestibular rehabilitation exercises: ball toss, lying-to-standing, target-change, thumb-tracking, tightrope, walking turns (7)[B]
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Balance exercises should be adhered to for symptom reduction and return to normal activities of daily living (ADLs).

Patient Monitoring
After 1 to 2 weeks, assess for the following:
- Recurrence of symptoms
- New-onset symptoms
- Medication-related adverse effects
- Relief from vestibular rehabilitation exercises

DIET
- Restricted salt intake for Ménière disease
- Dietary modifications for vertiginous migraine
- Heart healthy diet for CVD

PATIENT EDUCATION
- Reduce sodium intake (Ménière disease).
- Avoid triggers such as caffeine/alcohol (vertiginous migraine).

PROGNOSIS
Depends on diagnosis and response to treatment

COMPLICATIONS
- Anxiety
- Depression
- Disability
- Injuries from falls

- Algorithm: Dizziness

CODES

ICD10

- R42 Dizziness and giddiness
- H81.10 Benign paroxysmal vertigo, unspecified ear
- H81.49 Vertigo of central origin, unspecified ear

CLINICAL PEARLS

- TiTrATE your assessment.
- Acute, spontaneous, continuous vertigo with a normal horizontal head impulse, direction-changing nystagmus, and skew deviation (HINTS positive) is highly sensitive and specific for CVA.
- Episodic, triggered vertigo with positive Dix-Hallpike test is consistent with BPPV.
- If patient warrants a HINTS exam, do not perform Dix-Hallpike because central cause can also produce a positive Dix-Hallpike.
- The Epley maneuver is recommended for the treatment of BPPV.
- Medications are not recommended for BPPV.
VERTIGO, BENIGN PAROXYSMAL POSITIONAL (BPPV)
Chirag N. Shah, MD, FACEP  Kyung In Yoon, MD

BASICS

DESCRIPTION
- Benign paroxysmal positional vertigo (BPPV) is a mechanical disorder of the inner ear characterized by a brief period of vertigo experienced when the position of the patient’s head is changed relative to gravity.
- Vertigo results from the mismatch of the perception of movement by the visual, vestibular, and proprioceptive symptoms when none exist.
- The brief period of vertigo is caused by abnormal stimulation of ≥1 of the 3 semicircular canals of the inner ear, with the posterior canal most commonly affected.
- BPPV is the single most common cause of vertigo.

EPIDEMIOLOGY
- Lifetime prevalence is 2.4% and 1-year incidence 0.6%.
- Age of onset is most commonly between the 5th and 7th decades of life.
- Incidence increases with each decade of life.
- Prevalent sex: female > male
- BPPV affects the quality of life of elderly patients and is associated with reduced activities of daily living scores, falls, and depression.

Prevalence
- Common
- Lifetime prevalence 2.4% with 1-year incidence 0.6%

ETIOLOGY AND PATHOPHYSIOLOGY
- In BPPV, calcite particles (otoconia) that normally weight the sensory membrane of the maculae become dislodged and settle into the semicircular canal, changing the dynamics of the canal. Reorientation of the canal relative to gravity causes the otoconia to move to the lowest part of the canal, causing displacement of the endolymph, deflection of the cupula, and activation of the primary afferent. This results in the generation of nystagmus and the associated sensation of vertigo.
- BPPV may be idiopathic, posttraumatic, or associated with viral neurolabyrinthitis.

DIAGNOSIS
- The diagnosis is established based on history and findings on positional testing, clarified by Dix and Hallpike in 1952 (1,2)[A].
- Positional tests place the plane of the canal being tested into the plane parallel with gravity.

HISTORY
- Brief episodes of vertigo (sensation that the room is spinning) associated with
  - Rolling over in bed
  - Getting out of bed
– Looking up (referred to as “top-shelf syndrome”)
– Bending forward
– Quick head movements

- Patients may also complain of light-headedness or feeling “off balance.”
- Frequently, patients complain of nausea and, if severe enough, vomiting.

**PHYSICAL EXAM**

- The Dix-Hallpike test (DHT) is used to diagnose BPPV (1)[A]. The test provokes the characteristic nystagmus associated with the symptoms of vertigo, with an estimated sensitivity of 79% (95% CI 65–94) and specificity 75% (95% CI 33–100) (3)[B].
  - To perform the DHT, rapidly move the patient from seated to the supine position with the head turned 45 degrees to the right and held just over (below) the edge of the exam table. The position is maintained for 45 to 60 seconds. Observe for nystagmus and patient report of vertigo. Nystagmus/vertigo may not appear immediately. Wait until symptoms (4) resolve and then return the patient to the sitting position. Repeat on the left. The position is maintained for 45 to 60 seconds.
  - The direction of the fast phase of the nystagmus, along with any latency period before onset and duration of the nystagmus, before it ceases is recorded.
  - BPPV is consistent with a latency period of <30 seconds between lowering the head and the subsequent onset of nystagmus; the eye movements peak then slowly resolve within 40 seconds. The direction of the nystagmus reverses when the patient’s head is brought back upright and to the neutral position. Repeated testing results in diminished vertiginous symptoms and nystagmus fatigue.
  - The following characteristics help to distinguish a peripheral etiology for the patient with vertigo versus a central cause:
    - Onset is sudden (versus sudden or slow)
    - Severity is intense spinning (versus less intense)
    - Pattern is paroxysmal (versus constant)
    - Symptoms are aggravated by movement (versus variable)
    - Nausea or diaphoresis is frequent (versus variable)
    - Nystagmus has rotatory-vertical, horizontal eye movements (versus vertical)
    - Symptoms fatigue (versus ongoing)
    - Hearing loss or tinnitus may occur (versus not typically an associated symptom)
    - An abnormal TM may be seen (versus this is not an associated finding)
    - CNS symptoms are no associated (versus CNS findings usually present)
  - Red flags in vertigo
    - Neurologic deficit, ipsilateral hearing loss, gait abnormality, direction-changing nystagmus

- Head Impulse Nystagmus Test of Skew (HINTS)
  - Head impulse test of vestibulo-ocular reflex function
    - Normally, eye movement will correct with rapid head movement so that the center of the vision remains on a target. This reflex fails in peripheral causes of vertigo.
    - Have patient fix their eyes on your nose, and move their head in the horizontal plane to the left and then to the right.
    - When the head is turned toward the normal side, the vestibulo-ocular reflex remains intact and eyes are fixated on the examiner’s nose.
    - When the head is turned toward the affected side, the vestibulo-ocular reflex fails and the eyes make a corrective saccade to refixate on the examiner’s nose.
It is reassuring if the reflex is abnormal (due to dysfunction of the peripheral nerve).

- Nystagmus in primary, right, and left gaze
- Test for skew deviation “vertical dysconjugate gaze.”

- Skew deviation is a fairly specific predictor of central lesion in patients with acute vestibular syndrome.
- The presence of skew may help identify stroke when a positive head impulse test falsely suggests a peripheral lesion.
- Have patient look at your nose with their eyes and start by covering one eye and then rapidly move to cover the other eye, do this rapidly back and forth.
- When each eye is uncovered, quickly look to see if the eye has movement or refixation. Horizontal is normal, vertical is not.

- In the setting of dizziness and vertigo, HINTS substantially outperforms ABCD2 for stroke diagnosis and outperforms magnetic resonance imaging (MRI) obtained within the first 2 days after symptom onset (5)[B].

**DIFFERENTIAL DIAGNOSIS**

- Orthostatic hypotension and other disorders that cause low blood pressure; symptoms usually occur when the patient stands up.
- Damage to the brainstem or cerebellum can cause positional vertigo but is accompanied by other neurologic signs and usually has a different pattern of nystagmus.
- Low spinal fluid pressure may cause positional symptoms that are better when the patient lies down.
- Migraine-associated vertigo
- Traumatic brain injury
- Brain tumors
- Brain hemorrhage or infarction
- Vestibular neuronitis

**TREATMENT**

- The C-reactive protein (CRP) or Epley maneuver is effective in the treatment of posterior canal BPPV (1)[A]. Using a particle repositioning maneuver, the clinician moves the patient through a series of positions. In randomized controlled trials, the average short-term success rate of the CRP following one treatment session is 80% ± 9% (1)[A].
- The clinician moves the patient through a series of four provoking positions (6)[B]:
  - Placement of the right posterior canal (involved canal) in the right head-hanging position of the DHT
  - The head is then rotated a total of 90 degrees toward the left (uninvolved side) into 45 degrees of left head rotation.
  - Maintaining 45 degrees of left head rotation, the patient is rolled onto the left side (uninvolved side) with the head slightly elevated from the supporting surface.
  - The patient then sits up and flexes the neck 36 degrees. Each position is maintained for a minimum of 45 seconds or as long as the nystagmus lasts. The procedure is repeated 3 times.
- CRP is the best maneuver for posterior BPPV and should be offered to all age groups (7)[A].
- Semont maneuver is also another maneuver, less superior when performed alone (7)[A].
Contraindications are carotid stenosis, unstable cardiac disease, and severe neck disease. If the CRP is ineffective, self-administered CRP is performed at home (1)[A]. The patient performs the CRP on the bed with the head extended over the edge of a pillow. Better outcomes are achieved with a combination of CRP with self-administered CRP (1)[A].

• CRP and Semont are ineffective for horizontal BPPV; variations of the Lempert maneuver, barbecue roll, or Gufoni maneuver are widely used treatment methods for horizontal BPPV.
• Postmaneuver activity restrictions were previously advocated, but in controlled trials, it did not differ in clinical outcomes (2,7)[A].

MEDICATION
• Vestibular suppressant medications are not recommended for treatment of BPPV, other than for the short-term management of vegetative symptoms (3)[A].
• Antiemetics such as ondansetron (Zofran) may be considered for prophylaxis for patients who have had severe nausea or vomiting with the DHT.
• Vestibular suppressants such as benzodiazepines and antihistamine anticholinergics such as meclizine should be avoided because they may suppress nystagmus during the DHT and treatment.

ISSUES FOR REFERRAL
Consider a referral to a specialist if BPPV is unresponsive to treatment or if the patient is diagnosed with atypical BPPV involving the anterior or lateral canal. Consider referring to a physical therapist, neurologist, or an otolaryngologist.

ADDITIONAL THERAPIES
• Brandt-Daroff exercises and habituation exercises are not as effective as self-administered CRP. At 1 week, the average success rate for the Brandt-Daroff exercise is 23–24% compared with 90% for self-administered CRP (1)[A].
• Surgical intervention is rarely indicated, except for refractory BPPV, and includes posterior canal occlusion and singular neurectomy.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
The patient should follow up within a week after treatment to ensure resolution.

PATIENT EDUCATION
A number of illustrative YouTube videos are available for education and self CRP maneuvers.

PROGNOSIS
80% cure rate with CRP maneuvers, with a 30% recurrence rate at 1 year, and 44% redevelop BPPV within 2 years

COMPLICATIONS
During the maneuvers, a canal conversion may occur. The debris from the canal being treated may reflux into another canal.

REFERENCES

ADDITIONAL READING

CODES
ICD10
- H81.10 Benign paroxysmal vertigo, unspecified ear
- H81.12 Benign paroxysmal vertigo, left ear
- H81.11 Benign paroxysmal vertigo, right ear

CLINICAL PEARLS
- The diagnosis of BPPV is based on history and findings on positional testing.
- The typical presentation is a report of transient episodes of vertigo (sensation that the room is spinning) associated with a change in position of the head relative to gravity.
- BPPV may be treated effectively with particle-repositioning maneuvers in the office and at home.
- Vestibular suppressant medications and antiemetics are not recommended for treatment of BPPV, other than for the short-term management of symptoms.
- Patients should always be ambulated in to verify normal gait prior to discharge.
VINCENT STOMATITIS
Daniel V. Girzadas Jr., MD, RDMS ● Oluwaranti Aina Ositelu, MD, BS

BASICS

DESCRIPTION

- Inflammatory infection of the gingiva, characterized by pain, ulcerations, and necrotizing damage to interdental papillae
- Caused by an imbalance of oral flora, resulting in a predominance of invasive anaerobic bacteria, such as Fusobacterium, Prevotella intermedia, and spirochetes
- Concomitant infection with Epstein-Barr virus, herpes simplex virus, and type 1 human cytomegalovirus is common.
- Organisms invade gingiva and interdental papillae and form a gray pseudomembranous exudate.
- Clinical presentation includes pain, fetid breath, gingival ulcerations, bleeding, and interdental papillary necrosis. It is differentiated from other periodontal diseases by rapid onset, pain, ulcerated gingival mucosa, and “punched out” interdental papillary necrosis.
- Synonym(s): Vincent angina; trench mouth; acute necrotizing ulcerative gingivitis (ANUG)

EPIDEMIOLOGY

Incidence

- Predominant age: 18 to 30 years in developed countries
- Malnourished children ages 3 to 14 years
- Affects both genders with similar frequency
- Historically, incidence increased in military personnel exposed to battlefield conditions (1).

Prevalence

- Rare disease in developed countries.
- Prevalence is low in healthy children up to age 18 years.
- Prevalence is more common in persons ages 18 to 30 years. Prevalence increases with malnutrition, immunocompromised, poor oral hygiene, and smoking, or those from underdeveloped countries.

ETIOLOGY AND PATHOPHYSIOLOGY

- Impaired host immunologic response due to immunocompromised state or malnutrition
- Disruption of normal oral flora with predominance of invasive anaerobic bacteria
- Loss of integrity and necrosis of the gingival mucosa and interdental papillae
- Increased bacterial attachment with active herpesvirus infection

RISK FACTORS

- Malnutrition
- Immunosuppression (cancer, HIV infection)
- Tobacco use
- Poor oral hygiene
Infrequent or absent dental care
Orthodontics
Herpesvirus infection
Psychological stress

GENERAL PREVENTION
- Appropriate nutrition
- Proper oral hygiene
- Regular dental care
- Prompt recognition and institution of therapy
- Management of medical problems such as cancer and HIV infection
- Stress management

COMMONLY ASSOCIATED CONDITIONS
- Seen most commonly in malnourished patients, patients undergoing cancer treatment, or those from underdeveloped countries
- HIV infection
- Vitamin deficiencies
- Bacteremia
- Osteomyelitis
- Tooth loss
- Dehydration
- Noma (cancrum) oris, which can be life-threatening
- Aspiration pneumonia

DIAGNOSIS

HISTORY
- Acute onset of oral pain
- Gingival ulcerations
- Fetid odor of breath
- Bleeding and necrosis of interdental papillae
- Cervical adenopathy
- Fever
- Malaise
- Immunosuppression
- Chemotherapy
- Active herpesvirus infection or HIV

PHYSICAL EXAM
- Fetid odor of breath
- Ulceration of gingival mucosa
- Inflamed, erythematous gingiva
- Necrosis of interdental papillae
- Gingival bleeding
- Formation of gray, pseudomembranous exudate
- Cervical and submandibular lymphadenopathy
Fever and malaise may be present.

**DIFFERENTIAL DIAGNOSIS**
- Herpes simplex virus
- Periodontitis
- Recurrent aphthous stomatitis
- Medication side effects
- Oral malignancy
- Xerostomia
- Diphtheria
- Lymphoma/leukemia
- Primary syphilis
- Ascorbic acid deficiency
- Gingivitis
- Behçet disease
- Granulomatosis with polyangiitis
- Oral mucositis
- Erosive lichen planus

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
Diagnosis is primarily based on clinical exam, but if systemic illness or invasive spread to deeper tissue or bone is suspected, the following studies should be considered:
- Aerobic and anaerobic cultures of inflamed or débrided tissue
- Group A strep rapid antigen detection assay
- Group A strep throat culture
- Blood cultures if systemic involvement
- Dental radiographs
- CT imaging of the face and neck if infection has progressed

**TREATMENT**

**GENERAL MEASURES**
Elimination of tobacco, improved nutritional status, and improved immunologic status will increase rate of healing and reduce risk of future gingival disease.

**MEDICATION**
Most cases are treatable on outpatient basis. Severe disease with systemic effects and/or neck involvement requires inpatient treatment.

**First Line**
- Chlorhexidine gluconate 0.12% 15 mL 30 seconds rinse/spit QID (2)[C] and
- Penicillin V potassium 250 to 500 mg QID PO for 10 days; pediatric dosing: 25 to 50 mg/kg/day divided q6–8h or
- Metronidazole 500 mg q8h for 7 to 10 days (3)[C]; pediatric dosing: 30 mg/kg/day divided q6h or
- Amoxicillin 500 mg TID PO for 7 days (3)[C]; pediatric dosing: 25 to 45 mg/kg/day divided
q12h or
- Amoxicillin-clavulanate 875 mg q12h for 7 to 10 days (3)[C]; pediatric dosing: 25 to 45 mg/kg/day divided q12h (based on amoxicillin component)

**Second Line**
- Tetracycline 250 to 500 mg QID PO for 10 days (do not use for children <8 years of age); pediatric dosing: 25 to 50 mg/kg/day divided q6h or
- Erythromycin 250 to 500 mg QID PO for 10 days; pediatric dosing: 30 to 50 mg/kg/day divided q6–8h or
- Clindamycin 450 mg q8h for 7 to 10 days; pediatric dosing: 10 to 25 mg/kg/day divided q6–8h

**Pediatric Considerations**
- Chlorhexidine and alcohol mouth rinses are generally avoided due to risk of ingestion, but chlorhexidine may be prescribed in gel form for topical application.
- Metronidazole is first-line oral therapy (refer to dosing above) (4).

**ISSUES FOR REFERRAL**
Severe disease requires débridement by consultant dentist, oral surgeon, or ENT specialist.

**ADDITIONAL THERAPIES**
- Warm saline rinses q2h
- Sodium bicarbonate toothpaste, brush q2h
- Viscous lidocaine 2% 1 tbsp rinse/spit q6–8h
- NSAID medications q4–12h
- Opioid analgesics q4–6h (severe pain)
- Treatment of underlying immunodeficiency (if present)

**SURGERY/OTHER PROCEDURES**
- Débridement of inflamed/necrotic gingival tissue
- Dental extraction
- Gingival restoration
- Adjuvant therapies
  - Low-level laser therapy (LLLT) has been shown in one case series to decrease pain and accelerate healing (5)[C].

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
3% hydrogen peroxide and warm sterile saline in a 1:1 ratio 4 times a day as an oral rinse

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Severe disease, failure of oral antibiotics, or ongoing comorbidities
- Parenteral antibiotics and/or analgesia requirement
- Inability to tolerate PO

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Close dental follow-up
- Primary care follow-up
• Specialty follow-up (if underlying immunodeficiency)

DIET
• Soft diet until healed
• Balanced nutritional diet
• Multivitamin supplementation

PATIENT EDUCATION
• Proper nutrition
• Oral hygiene
• Tobacco cessation

PROGNOSIS
• With appropriate treatment, including chlorhexidine rinse, systemic antibiotics, débridement if necessary, and smoking cessation, infection usually completely resolves in 5–7 days.
• Maintenance of adequate oral hygiene is needed to prevent recurrence.

COMPLICATIONS
• Pain
• Malnutrition
• Gingival/tooth loss
• Deep infection of neck
• Systemic infection

REFERENCES

CODES
ICD10
A69.1 Other Vincent’s infections

CLINICAL PEARLS
• Immunosuppression, malnourishment, smoking, and poor oral hygiene are key risk factors for necrotizing ulcerative gingivitis.
• Diagnosis is largely clinical based on symptoms of oral pain, fetid breath, gingival ulcerations,
interdental papillary necrosis, and grayish exudate on the gingival surface.

- Most patients experience rapid improvement following appropriate treatment with chlorhexidine rinses, improved oral hygiene, and oral antibiotics.
- Smoking cessation and treatment of malnutrition or underlying illness are additional important treatment considerations.
- Severe disease requires débridement of necrotic gingival tissue.
VITAMIN B\textsubscript{12} DEFICIENCY
Sahil Mullick, MD ● Robin S. Chirackal, MBBS

**BASICS**
- Vitamin deficiency related to inadequate intake or absorption of cobalamin (vitamin B\textsubscript{12})
- Cobalamin is critical for central nervous system myelination and normal functioning.
- Deficiency can cause a multitude of symptoms and disorders including megaloblastic anemia, bone marrow dysfunction, and diverse and potentially irreversible neuropsychiatric changes.
- Neuropsychiatric disorders are due to demyelination of cervical, thoracic dorsal, and lateral spinal cords; demyelination of white matter; and demyelination of cranial and peripheral nerves.
- Low vitamin B\textsubscript{12} level can lead to elevated methylmalonic acid (MMA) and homocysteine levels.
- Elevated MMA and homocysteine levels (especially elderly, infants, and pregnant women be as early markers of vitamin B\textsubscript{12} deficiency (1).  
  - Elevated MMA causes abnormality in fatty acid synthesis affecting neuronal membrane.  
  - Elevated homocysteine is neurotoxic through overstimulation of the \textit{N}-methyl-\textit{d}-aspartate (NMDA) receptor and toxic to vasculature through activation of coagulation system and effects on endothelium.
- An elevated MMA and/or homocysteine values aids in establishing a possible diagnosis of the deficiency in people with borderline vitamin B\textsubscript{12} levels (i.e., those between 140 and 300 pmol/L).

**DESCRIPTION**
Normal B\textsubscript{12} absorption
- B\textsubscript{12} is a water-soluble vitamin present in animal-source foods (meat, fish, eggs, milk) and foods (cereals and supplements) fortified with B\textsubscript{12}.
- Dietary vitamin B\textsubscript{12} (cobalamin) bound to food is cleaved by acids in stomach and bound to haptocorrin (commonly known as R-factor).
- Duodenal proteases cleave B\textsubscript{12} from haptocorrin.
- In duodenum, B\textsubscript{12} uptake depends on binding to intrinsic factor (IF) secreted by gastric parietal cells.
- B\textsubscript{12}-IF complex is absorbed by terminal ileum into portal circulation.
- Body’s B\textsubscript{12} stored in liver = 50–90%  
  - B\textsubscript{12} secreted into bile from liver recycled via enterohepatic circulation  
  - Delay 5 to 10 years from onset of B\textsubscript{12} deficiency to clinical symptoms due to hepatic stores and enterohepatic circulation
- Typical Western diet: 5 to 30 μg/day; however, only 1 to 5 μg/day is effectively absorbed.  
  - Recommend 2.4 μg/day for adults and 2.6 μg/day during pregnancy and 2.8 μg/day during lactation (most prenatal vitamins contain B\textsubscript{12}).

**EPIDEMIOLOGY**
Prevalence
- Endemic area: Northern Europe, including Scandinavia; more common in those of African ancestry
- Increasing recognition in breastfed-only infant populations with vitamin B\textsubscript{12}–deficient mothers
- Prevalence 5–20% in developed countries
  - 12% in elderly living in community
  - 30–40% in elderly in institutions, sick, or malnourished
  - 5% patients in tertiary reference hospitals
- Prevalence by age group
  - <60 years old: prevalence 6%
  - >60 years old: prevalence 20%

ETIOLOGY AND PATHOPHYSIOLOGY
- Decreased oral intake
  - Vegetarians and vegans: B\textsubscript{12} is found in animal source foods; however, strict vegetarians uncommonly develop deficiency because only 1 mg/day is needed, with adequate amounts present in legumes.
- Decreased IF
  - Pernicious anemia (PA): can be associated with autoantibodies directed against gastric parietal cells and/or IF
  - Chronic atrophic gastritis: autoimmune attack on gastric parietal cells causing autoimmune gastritis and leading to decreased IF production
  - Gastrectomy: Removal of entire or part of stomach decreases number of parietal cells.
- Decreased absorption
  - Crohn disease: Terminal ileal inflammation decreases body’s ability to absorb B\textsubscript{12}.
  - Chronic alcoholism: decreases body’s ability to absorb B\textsubscript{12}
  - Gluten hypersensitivity (Celiac disease) causes intestinal villi atrophy and subsequent malabsorption
  - Ileal resection
  - Pancreatic insufficiency: Pancreatic proteases are required to cleave the vitamin B\textsubscript{12}–haptocorrin bond to allow vitamin B\textsubscript{12} to bind to IF.
  - Helicobacter pylori infection: impairs release of B\textsubscript{12} from bound proteins
- Medications:
  - Proton pump inhibitors (PPIs), H\textsubscript{2} antagonists, and antacids decrease gastric acidity, inhibiting B\textsubscript{12} release from dietary protein; metformin
  - Metformin usage
    - Chronic metformin usage leads to vitamin B\textsubscript{12} deficiency. Caused by calcium-dependent membrane inhibition, interfering with vitamin B\textsubscript{12}–IF absorption. Years on metformin is the only predictive factor for B\textsubscript{12} deficiency.
    - Metformin use was associated with an increase in MMA and worsening neuropathy score in patients with type 2 diabetes.
- Hereditary (rare)
  - Imerslund-Gräsbeck disease (juvenile megaloblastic anemia)
  - Congenital deficiency of transcobalamin
  - Severe methylene tetrahydrofolate reductase deficiency
Abnormalities of methionine synthesis
Mutations in the gene for intrinsic factor, genes encoding the vitamin B\(_{12}\) transporting transcobalamin, and genes involving intracellular vitamin B\(_{12}\) metabolism.

**Causes:**
- Food-cobalamin malabsorption syndrome
  - As many as 60–70% of cases
  - Primary cause in elderly
  - Pathophysiology: inability to release cobalamin from food or binding protein, especially if in the setting of hypochlorhydria
  - Seen in atrophic gastritis, long-term ingestion of antacids and biguanides, possible relationship to H. pylori infection
- Pernicious anemia
  - 15–30% of all cases; most frequent cause of severe disease. Neurologic disorders are common presenting complaints.
  - Common in elderly, as high as 20%, with mild atrophic gastritis, hypochlorhydria, and impaired release of dietary vitamin B\(_{12}\)
  - Autoimmune disease with destruction of gastric fundal mucosa cells via a cell-mediated process
  - Antigastric parietal cell antibodies: sensitivity >90%, specificity 50%; use for screening test
  - Anti-IF antibodies: sensitivity 50%
  - Associated with other autoimmune diseases
- Insufficient dietary intake: 2% of cases; vegans or long-standing vegetarians
- Infants born to vitamin B\(_{12}\)-deficient mothers may have deficiency or may develop it if breastfed exclusively.
- Intestinal causes:
  - 1% of cases; prevalence depends on risk factors, such as surgical conditions.
  - Gastrectomy: due to decreased production of IF
  - Gastric bypass: appears 1 to 9 years after surgery, prevalence 12–33%
  - Ileal resection or disease
  - Fish tapeworm
  - Severe pancreatic insufficiency
- Undetermined etiology
  - 1/10 of cases

**Genetics**
Imerslund-Gräsbeck disease (juvenile megaloblastic anemia) caused by mutations in the amnionless (AMN) or cubilin (CUBN) genes with autosomal recessive pattern of inheritance; inadequate ileal uptake of B\(_{12}\)-IF complex and B\(_{12}\) renal protein reabsorption

**GENERAL PREVENTION**
Risk factors: vegan diet, age >60 years, female, chronic atrophic gastritis, Crohn disease or other ileal disorders, chronic medication use including PPI, metformin, H\(_2\) antagonists
DIAGNOSIS

Symptoms and physical exam findings:
- Asymptomatic patients may be diagnosed by the incidental finding of anemia or an elevated mean corpuscular volume (MCV) during routine testing or evaluation of unassociated disorders.
- Hematologic
  - Frequent: macrocytosis, neutrophil hypersegmentation, spinal cord medullar megaloblastosis (blue spinal cord)
  - Rare: isolated thrombocytopenia and neutropenia, pancytopenia
  - Very rare: hemolytic, thrombotic microangiopathy with schistocytes
- Neuropsychiatric
  - Frequent: sensory polyneuritis, paresthesias, positive Babinski sign, weakness, gait unsteadiness, loss of proprioception (impaired vibratory sensation, positive Romberg, ataxia, hyperreflexia)
  - Classic but uncommon: subacute combined degeneration of spinal cord associated with PA; myelin degeneration in the lateral and posterior columns; areflexia (which may be permanent if neuronal death occurs in the posterior or lateral spinal cord tracts), ataxia, proprioception and vibration loss, bowel and bladder incontinence, orthostatic hypotension, decreased memory, mania, delirium, psychosis, depression
- Digestive
  - Classic: Hunter glossitis, jaundice, and high lactate dehydrogenase and bilirubin
  - Possible: abdominal pain, dyspepsia, nausea, vomiting, diarrhea
  - Rare: mucocutaneous ulcers
- Other
  - Frequent: fatigue with exertion, skin pallor, palpitations, edema, jaundice
  - Under investigation: chronic vaginal and urinary infections, atrophy of vaginal mucosa, hypoferlity, venous thromboembolism, angina, miscarriages
  - Commonly insidious and nonspecific; thus, delay in diagnosis is common.

HISTORY
- Underlying disease associated with vitamin B₁₂ deficiency
- Fatigue, anorexia
- Depression
- Falls (due to diminished proprioception)
- Loss of sensation in “stocking-glove” distribution
- Glossitis/loss of sense of taste and other subtle, nonspecific neurologic symptoms

DIAGNOSTIC TESTS & INTERPRETATION
- Measurement of vitamin B₁₂, complete blood count (MCV)
- Measurement of B₁₂ may be low or low normal depending on institution’s cutoff value.
  - 95–97% sensitive levels <200 pg/mL
  - May need additional tests such as MMA and homocysteine if vitamin B₁₂ level is low normal (<350 pg/mL) and no evidence of anemia depending on clinical suspicion
- If high suspicion on normal B₁₂ with high/normal MCV, consider testing MMA and homocysteine levels.
● MCV often increased
● Measurement of MMA
  – More sensitive and specific than homocysteine
  – Levels increased in renal failure and volume depletion.
● Measurement of homocysteine
  – Levels increased in folate deficiency, renal failure, homocystinuria. Vitamin B₆ deficiency and hypothyroidism (1)
● MMA and homocysteine levels only reliable in an untreated patient because levels fall with supplementation
● Other tests: folate and other markers of anemia (iron studies)
● MCV may be normal, decreased, or increased if vitamin B₁₂ deficiency coexists with other forms of anemia, such as iron deficiency or hemolysis. Thus, RBCs may be normochromic, normocytic, or hypochromic microcytic.
● Holotranscobalamin (holo-TC) accounts for approximately 10% of the circulating vitamin B₁₂ and is the earliest marker showing vitamin B₁₂ depletion. It is also known as active B₁₂ which is the only form of vitamin B₁₂ that is taken up and used by the cells in the body.

**ALERT**
● Low levels of vitamin B₁₂ are seen in folate deficiency, HIV, and multiple myeloma.
● Elevated levels of vitamin B₁₂ are seen in renal disease, occult malignancy, and alcoholic liver disease and as a result of technical error.
● Macrocytosis may be due to folate deficiency, reticulocytosis, medications, bone marrow dysplasia, and hypothyroidism or be masked by concomitant microcytic anemia.
● Serum homocysteine and MMA
  – Elevated in B₁₂ deficiency secondary to decreased metabolism
  – If both are normal, B₁₂ deficiency is effectively ruled out.
  – If MMA is normal and homocysteine is increased, think folate deficiency.
● In some individuals without symptoms, vitamin B₁₂ deficiency may be associated with reductions in the binding protein haptocorrin. However, this condition may be difficult to discriminate from true vitamin B₁₂ deficiency in the presence of symptoms.
● PA
  – Check antibody to IF; positive test is confirmatory for PA, but sensitivity is only 50–70%.
  – Antiparietal cell antibody positivity indicates PA.
  – For patients who are antibody positive, consider screening for autoimmune thyroid disease.
  – For patients with negative anti-IF result and high suspicion for PA, check serum gastrin level (elevated level is consistent with diagnosis of PA).

**Pregnancy Considerations**
● Because B₁₂ crosses the placenta, pregnant women with low levels of B₁₂ are at higher risk of having children with neural tube defects, developmental delay, failure to thrive, hypotonia, ataxia, and anemia.
● Exclusively breastfed infants of mothers who are B₁₂ deficient are at risk of developing B₁₂ deficiency. Infants breastfed from B₁₂-deficient mothers might not show signs or symptoms until 4 to 6 months of age, which may include developmental regression, feeding difficulties, lethargy, or hypotonia.
Maternal vitamin B₁₂ deficiency during pregnancy can lead to an increased incidence of neural tube defects, brain development retardation, as well as preterm birth and low birth weight.

**ALERT**
Children born to mothers with normal to high folate levels and low serum vitamin B₁₂ values have higher truncal adiposity and insulin resistance which may influence long-term risk of development of type 2 diabetes and cardiovascular disease.

- Insufficient vitamin B₁₂ status has an important negative influence on children’s development and cognitive functioning.
- Nutritional vitamin B₁₂ deficiency and late diagnosis of this condition in children may cause irreversible neurologic damage such as growth and motor retardation and even convulsions.
- High suspicion of vitamin B₁₂ deficiency is warranted in women with risk factors including obesity, prior bariatric surgery, inflammatory bowel disease, Helicobacter pylori infection, use of metformin or proton pump inhibitors, and certain vegan diets.
- Untreated severe vitamin B₁₂ deficiency during pregnancy can have profound effects including severe anemia, peripheral neuropathy, cognitive decline, and a variety of neuropsychiatric manifestations.
- It may also manifest with microangiopathic hemolytic anemia and thrombocytopenia, mimicking other thrombotic microangiopathy (TMA) disorders such as atypical hemolytic uremic syndrome (aHUS), hemolysis, elevated liver enzymes, low platelet count (HELLP) syndrome, and thrombotic thrombocytopenic purpura.

**Diagnostic Procedures/Other**
Bone marrow exam is usually unnecessary.

### TREATMENT

**MEDICATION**
- Parenteral cyanocobalamin replacement recommended in patients with severe neurologic symptoms: IM cyanocobalamin
  - 1,000 μg/day for 7 days, then
  - 1,000 μg weekly for 4 weeks, then
  - 1,000 μg monthly for life
- High-dose, daily oral cyanocobalamin at doses of 1,000 to 2,000 μg are as effective as monthly intramuscular injection and is the preferred route of initial therapy in most circumstances because it is cost-effective and convenient. Requires greater patient compliance.
- Severe vitamin B₁₂ deficiency reported with nitrous oxide.

**ALERT**
Folic acid without vitamin B₁₂ in patients with PA is contraindicated; it will not correct neurologic abnormalities.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Consider blood transfusion for severe anemia.
ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Hematologic
  - Reticulocytosis in 1 week
  - Rise in hemoglobin beginning at 10 days; usually will return to normal in 6 to 8 weeks
  - Monitor potassium in profoundly anemic patients (hypokalemia due to potassium use).
  - Serum MMA decreases with replacement therapy.
- Neurologic: can note improvement within 6 weeks to 3 months of treatment; however, maximum improvement noticed at 6 to 12 months. Some symptoms may be irreversible.

DIET
Meat, animal protein, and legumes unless contraindicated

REFERENCES

ADDITIONAL READING

CODES

ICD10

- E53.8 Deficiency of other specified B group vitamins
- D51.0 Vitamin B12 defic anemia due to intrinsic factor deficiency
- D51.3 Other dietary vitamin B12 deficiency anemia

CLINICAL PEARLS

- Vitamin B_{12} deficiency can coexist with other anemia, thus, MCV can be normal, decreased, or increased.
- For PA, cyanocobalamin must be lifelong.
VITAMIN D DEFICIENCY
Frank J. Domino, MD  Samir Malkani, MD, MRCP–UK

BASICS
This topic covers the commonly acquired vitamin D deficiency and not type II vitamin D–resistant rickets/type I pseudovitamin D–resistant rickets (both rare autosomal recessive disorders).

DESCRIPTION
- Vitamin D is a hormone and a vitamin.
- Cholecalciferol (D$_3$) is synthesized in the skin by exposure to ultraviolet B (UV-B) radiation. Ergocalciferol (D$_2$) and D$_3$ are present in foods.
- D$_2$ and D$_3$ are hydroxylated in the liver to 25 vitamin D (calcidiol), the major circulating form.
- Calcidiol is further hydroxylated in the kidney to the active metabolite 1,25 vitamin D (calcitriol).
- Hypocalcemia stimulates parathyroid hormone (PTH) secretion, which prompts increased conversion of 25 vitamin D to 1,25 vitamin D.
  - 1,25 vitamin D decreases renal calcium and phosphorus excretion, increases intestinal calcium and phosphorus absorption, and increases osteoclast activity. The net result is an increase in serum calcium.

EPIDEMIOLOGY
- A community cohort study of asymptomatic adolescents in Boston found 24% were deficient, with 5% severely deficient.
- A study of hospitalized patients in Massachusetts found 57% vitamin D–deficient (VDD).
- Women with history of osteoporosis/osteoporotic fracture have high prevalence of vitamin D deficiency.
- A cohort study in Arizona found >25% of adults were VDD; highest rates among African Americans and Hispanics.
- A study of about 56,000 individuals across Europe found 13% to have vitamin D deficiency.

Pediatric Considerations
National Health and Nutrition Examination Survey (NHANES) data suggest 70% of children do not have sufficient 25-OH vitamin D serum levels (9% deficient and 61% insufficient); deficiency has been associated with an increase in BP and decrease in high-density lipoprotein (HDL) cholesterol.

ETIOLOGY AND PATHOPHYSIOLOGY
- Insufficient dietary intake of vitamin D and/or lack of UV-B exposure (in sunlight) results in low levels of vitamin D.
  - This limits calcium absorption, causing excess PTH release.
- PTH stimulates osteoclast activity, which helps to normalize calcium and phosphorous but results in osteomalacia.
- Dietary deficiency
  - Inadequate vitamin D intake
Inadequate sunlight exposure
  – Institutionalized/hospitalized patients
• Chronic illness: liver/kidney disease
• Malabsorptive states

Genetics
Vitamin D–dependent rickets type 1 occurs due to inactivating mutation of the 1α hydroxylase gene; as a result, calcidiol is not hydroxylated to calcitriol.

RISK FACTORS
• Inadequate sun exposure
• Female
• Dark skin
• Immigrant populations
• Low socioeconomic status
• Latitudes higher than 38 degrees
• Elderly
• Institutionalized
• Depression
• Medications (phenobarbital, phenytoin)
• Gastric bypass surgery/malabsorption syndromes
• Obesity
• Rates higher in black and Hispanic populations

GENERAL PREVENTION
• Adequate exposure to sunlight and dietary sources of vitamin D (plants, fish); many foods are fortified with vitamin D$_2$ and D$_3$.
• Recommended minimum daily requirement is 600 IU/day from age 1 to 70 years and 800 IU/day for those >70 years. Up to 4,000 IU/day is safe in healthy adults without risk of toxicity.
• For ages 51 to 70 years, minimally recommended supplementation is 800 IU/day to prevent nonvertebral fractures.

Pediatric Considerations
• The American Academy of Pediatrics recommends all breastfed babies receive 400 IU/day of vitamin D beginning “within the first few days of life.”
• 2016 Global Consensus Recommendations suggest all infants, regardless of feeding method, begin vitamin D 400 IU within a few days of birth (1).
• Mid-Gestational vitamin D deficiency doubled risk of Autism Spectrum Disorder in European cohort (2)

Pregnancy Considerations
Insufficient data to recommend routine screening of all pregnancies; only “at risk” should be screened; it is safe to take 1,000 to 2,000 IU/day during pregnancy (3)[B].

COMMONLY ASSOCIATED CONDITIONS
• Osteomalacia, osteoporosis
• Premenstrual syndrome
- Rickets
- Celiac disease
- Gastric bypass
- Chronic renal disease
- Bacterial vaginosis in pregnant women
- Hypertension
- Cohort study found that vitamin D deficiency is correlated with increased risk of all-cause mortality.

**ALERT**

Vitamin D deficiency is associated with risk of myocardial infarction (MI) and all-cause mortality (4)[A].

**DIAGNOSIS**

- Nonspecific musculoskeletal complaints
- Weak antigravity muscles
- Fracture with minimal trauma

**HISTORY**

- Senior citizens at risk of falling
- Renal disease
- GI (malabsorption) disorders
- Liver dysfunction
- Immigration from tropical to colder climates
- Dark-skinned/veiled individuals
- Housebound patients
- Women at perimenopause

**PHYSICAL EXAM**

- Vague neurologic signs: numbness, proximal myopathy, paresthesias, muscle cramps, laryngospasm
- Chvostek sign: contraction of the facial muscles by tapping along the facial nerve
- Trousseau phenomenon: carpal spasms and paresthesia produced by pressure on nerves and vessels of the upper arm, by inflation of a BP cuff
- Tetany, seizures
- Bowed legs

**DIFFERENTIAL DIAGNOSIS**

- Malabsorptive disease (e.g., celiac disease)
- Malnutrition

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Only test those at increased risk of deficiency (those lacking dietary exposure, sun exposure, etc.).
- 25-OH vitamin D (most sensitive measure of vitamin D status)
Vitamin D deficiency: <20 ng/mL
PTH elevation: not routinely obtained unless severe deficiency
Low-normal/low calcium and phosphorous
Elevated alkaline phosphatase (in later disease)
Plain radiographs: If atypical fracture, radiographs may show osteomalacia (pseudofractures/looser zones) in pelvis, femur, and fibula.

Osteoporosis screen
- Women ≥65 years with no risk factors
- Women ≥60 years at risk: body weight <70 kg (best predictor)
- Less evidence: smoking, low body mass index, family history, decreased activity, alcohol or caffeine use
- African American women have higher bone density than Caucasians.

**TREATMENT**

- Treatment goals remain unclear, but current “normal” 25-OH vitamin D levels are based on suppression of PTH.
- Obesity: Treatment of VDD in obesity, especially those who are obese and depressed, improves depressive symptoms and may improve weight loss.

**ALERT**
All-cause mortality: Cochrane Systematic Review found vitamin D supplementation lowers all-cause mortality (5)[A].

**Geriatric Considerations**
In senior citizens, serum 25-OH vitamin D of 20 ng/mL resulted in improved physical performance scores; recent data suggest supplementation may not improve fracture risk and remain unclear about a true benefit.

**MEDICATION**
- Vitamin D sufficient (25-OH vitamin D ≥20 ng/mL)
  - Vitamin D 800 to 2,000 IU/day D₂/D₃
  - D₃ (animal derived) may be slightly more effective than D₂ (plant derived), but clinical significance is uncertain.
  - Calcium supplementation: unclear benefit and may increase some congenital heart disease risk in patients; no supplementation currently required (see below)
- Vitamin D deficiency (25-OH vitamin D <20 ng/mL)
  - D₂ 50,000 IU/week for 8 to 12 weeks, followed by 800 to 2,000 IU/day of vitamin D₃
- Calcium: meta-analysis data support
  - Dietary intake of ~700 mg/day leads to best outcomes; higher doses did not decrease risk of osteoporotic fractures.
  - Dietary calcium may be more beneficial than calcium supplementation.
  - Supplementary calcium associated with an increased risk of MI, especially in women, but these data remain controversial.
  - Supplementation of vitamin D and calcium may increase risk of renal stone formation.

**ISSUES FOR REFERRAL**
Endocrinology if no response to treatment

ADDITIONAL THERAPIES
Aggressive calcium in ICU patients with ionized calcium <3.2 mg/dL or if symptomatic (tetany, seizures, QT prolongation, bradycardia, or hypotension or ventilated patient with decreased diaphragmatic function)

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Symptoms of severe hypocalcemia
- Malabsorption syndromes

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Follow-up of abnormal 25-OH vitamin D not required

DIET
- Cod liver oil is most potent source of vitamin D and has ~1,300 IU vitamin D/tablet/tablespoon.
- Fatty fish (tuna, salmon)
- Fortified milk (100 IU/8 oz), cereal, and foods

PROGNOSIS
- Cancer
  - Systematic review of 63 observational studies found adequate 25-OH vitamin D levels correlate with lower rates of colon, breast, and prostate cancer.
  - Observational data show inverse relationship between serum 25-OH vitamin D levels and breast cancer.
  - Serum level >30 ng/ml lowers risk of bladder cancer (6)
  - Vitamin D supplementation lowers cancer mortality but not all-cause mortality (7).
- Upper respiratory infections: Vitamin D supplementation lowers risk of URI (9)
- Other outcomes: may lower pain scores in osteoarthritis of the knee, decrease PMS symptoms, and improve depression symptoms

REFERENCES

CODES
ICD10
- E55.9 Vitamin D deficiency, unspecified
- M83.8 Other adult osteomalacia

CLINICAL PEARLS
- Common risk factors for vitamin D deficiency include inadequate sun exposure or dietary intake; obesity; and black or Hispanic ethnicity and obesity.
- 25-OH vitamin D (most sensitive measure of vitamin D status) is the most sensitive laboratory test for diagnosis.
- Vitamin D deficiency is defined by serum levels <20 ng/mL.
- Up to 2,000 IU/day of supplemental vitamin D is safe in healthy adults without risk of toxicity.
- The American Academy of Pediatrics recommends all breastfed babies receive 400 IU/day of vitamin D beginning within a few days of birth.
BASICS

DESCRIPTION

- Vitamins are essential micronutrients required for normal metabolism, growth, and development.
- Deficiencies are less common in the Western world, but certain populations are at increased risk.
- Regulations mandating vitamin supplementation in food products, adequate food security, and availability of vitamin supplements make vitamin deficiencies less common in developed countries.
- Toxicity is rare for water-soluble vitamins; toxicity is possible with fat-soluble vitamins (A, D, E, K).

EPIDEMIOLOGY

Incidence

- Predominant age
  - Geriatric patients, pregnant women, exclusively breastfed infants, and individuals with certain chronic disease states have higher incidence
- Individuals from Africa and Southeast Asia are at increased risk.
- True incidence is unknown because most vitamin deficiencies are asymptomatic.

Prevalence

- Varies by age groups, comorbid conditions, geography, and setting (i.e., urban, rural)
- The prevalence of vitamin B₁₂ deficiency is ~6% in patients <60 years of age and increases to around 20% after age 60 years (1).
- Vitamin D deficiency prevalence is increased in individuals with darker skin pigmentation, obesity, low dietary intake of vitamin D, or low sunlight exposure.

ETIOLOGY AND PATHOPHYSIOLOGY

- Disease-related deficiency can develop under healthy conditions, generally due to one of five mechanisms:
  - Reduced intake
  - Diminished absorption
  - Increased use
  - Increased demand
  - Increased excretion
- Chronic disease states: HIV, malabsorption (such as celiac sprue and short bowel syndrome), chronic liver and kidney disease, alcoholism, malignancies, pernicious anemia, and inborn errors of metabolism
- Bariatric surgeries: gastric bypass, gastrectomy, small or large bowel resection
- Related to certain drugs: prednisone, phenytoin, isoniazid, protease inhibitors, methotrexate, phenobarbital, alcohol, nitrous oxide, H₂ receptor antagonists, metformin, colchicine,
cholestyramine, 5-fluorouracil, 6-mercaptopurine, azathioprine, chloramphenicol, proton pump inhibitors, chronically used antibiotics, penicillamine, and hydralazine

- Malnutrition, imbalanced nutrition, obesity, fad diets, extreme vegetarianism, total parenteral nutrition, bulimia/anorexia, and other eating disorders
- Dialysis
- Parasitic infestation

**Genetics**
- Cystic fibrosis
- Hartnup disease
- Rare genetic predisposition
  - Autoimmune disease (e.g., pernicious anemia)
  - Congenital enzyme deficiencies (e.g., biotinidase or holocarboxylase synthetase deficiency)
  - Transcobalamin II deficiency
  - Ataxia with vitamin E deficiency (AVED)
- A-β-lipoproteinemia

**RISK FACTORS**
Poverty, malnutrition, chronic disease states, advanced age, dietary restrictions, bariatric surgery, certain medications, and exclusively breastfed infants

**GENERAL PREVENTION**
- Ingesting large and varied amounts of vitamin supplements increases risk of toxicity and drug–drug interactions and is not recommended.
- Antioxidant supplements have not been shown to impact cancer incidence and have increased mortality risk in some studies (2).
- Avoiding restrictive diets.
- U.S. Preventive Services Task Force (USPSTF) recommends against low-dose supplementation with vitamin D (<400 IU) and calcium (<1,000 mg) to reduce fracture risk in community-dwelling postmenopausal women (3).
- The USPSTF concludes that there is insufficient evidence to assess the balance of the benefits and harms of daily supplementation with doses greater than 400 IU of vitamin D and greater than 1,000 mg of calcium for the primary prevention of fractures in community-dwelling, postmenopausal women (3).
- The USPSTF also concludes that the current evidence is insufficient to assess the balance of the benefits and harms of vitamin D and calcium supplementation, alone or combined, for the primary prevention of fractures in men and premenopausal women (3).
- USPSTF recommends that all women planning or capable of pregnancy take a daily supplement containing 0.4 to 0.8 mg of folic acid (4)[A].
- USPSTF recommends against the use of β-carotene or vitamin E supplements for the prevention of cardiovascular disease or cancer (2).
- All infants should receive 400 IU/day of vitamin D soon after birth whether breast or formula fed (5).

**COMMONLY ASSOCIATED CONDITIONS**
Anemia, neuropathies, dermatitis, visual disturbances
DIAGNOSIS

HISTORY
- Review dietary intake.
- Decreased visual acuity or night blindness
- Poor wound healing or easy bruising
- Skin changes or new rash
- Neuropathy
- Abnormal food cravings (pica)
- Osteomalacia or history of low-energy fracture
- Previous birth of a child with spina bifida
- Previous gastrointestinal (GI) or bariatric surgery (1)
- Recurrent or persistent vomiting or diarrhea
- Prior or current medical conditions
  - Tuberculosis (TB), HIV infection, hepatitis, cancer
  - Hypermetabolic state
    - Thyrotoxicosis
    - 2nd- or 3rd-degree burns
    - Extensive or chronic wound
    - Any systemic infection
- Chronic disease requiring steroids, disease-modifying antirheumatic drugs (DMARDs), or immunosuppressants
- Malabsorptive or chronic GI disorder: celiac disease, sprue, Crohn disease, ulcerative colitis, gastroesophageal reflux disease
- Parenteral or enteral nutrition via tube feeding
- Pregnancy
- Amenorrhea or infertility issues
- Medications, supplements
- Food allergies or intolerances, fad or restrictive diet

PHYSICAL EXAM
- Neurologic exam: gait, memory/cognitive impairment, reflexes, sensory or motor impairment, peripheral neuropathy (1)
- Oropharyngeal exam: glossitis, bleeding gums, hyperemic pharynx, stomatitis, cheilitis (1)
- Skin exam: papulosquamous dermatitis, photosensitive pigmented dermatitis, ecchymosis, and/or petechiae
- Visual assessment

DIFFERENTIAL DIAGNOSIS
Multiple conditions mimic signs and symptoms of vitamin deficiencies.
- Diabetes mellitus (DM), thyroid disorders, hyperparathyroidism, heart failure, Alzheimer disease, multiple sclerosis, substance abuse, toxic ingestions, and hematologic disorders/malignancies

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- No routine screening indicated
Test if symptomatic, history indicates high risk, or if clinical characteristics are present:
- 25-OH vitamin D (5)
- Prothrombin time (PT)/partial thromboplastin time (PTT)
- Vitamin B$_{12}$ and folate levels (1)
- Serum homocysteine and methylmalonic acid levels if high suspicion of vitamin B$_{12}$ deficiency with normal serum B$_{12}$ level
- Retinol serum level, retinol-binding protein

Ancillary tests:
- Blood urea nitrogen, calcium, phosphorus, magnesium
- Albumin, liver function tests
- Complete blood count
- Parathyroid hormone

Bone densitometry for:
- Women 65 years of age or older without previous known fractures or risk factors
- Women <65 years old whose 10-year fracture risk is equal to that of a 65-year-old white woman without additional risk factors

Bariatric surgery patients are at risk for deficiencies. Laparoscopic gastric banding is less frequently associated with vitamin deficiencies.

Cyanocobalamin, thiamine, vitamin A

Disease states from vitamin deficiency
- Vitamin A (retinol): night blindness, complete blindness, xerophthalmia
- Vitamin B$_1$ (thiamine)
  - Wernicke encephalopathy: acute syndrome with memory disturbance, truncal ataxia, nystagmus, ophthalmoplegia
  - Korsakoff syndrome: anterograde and retrograde amnesia, confabulation
  - Dry beriberi: symmetric motor and sensory peripheral neuropathy, paresthesias, loss of reflexes
  - Wet beriberi: neuropathy with cardiovascular symptoms of peripheral vasodilation, high-output failure, dyspnea, and tachycardia
  - Infantile beriberi: loud piercing cry, cyanosis, tachycardia, cardiomegaly, dyspnea, vomiting, seizures
- Vitamin B$_2$ (riboflavin): glossitis, stomatitis, cheilitis, hyperemia of the pharyngeal mucosal membranes, normocytic-normochromic anemia
- Vitamin B$_3$ (niacin): pellagra: photosensitive pigmented dermatitis, dementia, and diarrhea
- Vitamin B$_5$ (pantothenic acid): paresthesias and dysesthesias, anemia
- Vitamin B$_6$ (pyridoxine): dermatitis, cheilosis, atrophic glossitis, stomatitis, neuropathy
- Vitamin B$_9$ (folate): megaloblastic anemia, rarely manifest neurologic symptoms
- Vitamin B$_{12}$ (cobalamin): pernicious anemia, leukopenia, pancytopenia, shuffling broad-based gait, atrophic glossitis, loss of vibration and position sense, cognitive impairment, areflexia, olfactory impairment, peripheral neuropathy, hyperpigmentation, jaundice, vitiligo
- Vitamin C (ascorbic acid): scurvy: ecchymoses, bleeding gums, petechiae, hyperkeratosis, arthralgias, impaired wound healing
- Vitamin D (calciferol): rickets, osteomalacia
- Vitamin E: neuromuscular disorders and hemolysis
– Vitamin K: easy bruising, mucosal bleeding, melena, hematuria
– Biotin: changes in mental status, dysesthesias, nausea, papulosquamous dermatitis of the extremities

**TREATMENT**

Although vitamin D deficiency has been linked with worse cardiovascular morbidity and mortality and is associated with vascular dysfunction; arterial stiffening; left ventricular hypertrophy; and worsened metrics of diabetes, hypertension, and hyperlipidemia, a causal effect between deficiency and cardiovascular disease has not been shown. Trials have failed to show improvements in blood pressure, insulin sensitivity, or lipids (6).

**MEDICATION**

- Ask patients supplement use; encourage patients to bring in vitamin and supplement bottles for review.
- Assess for potential adverse drug effects/reactions. Patients with alcohol use disorders should receive thiamine, folic acid, and MVI.
- Give patients with suspected thiamine deficiency 100 mg thiamine prior to IV fluids containing glucose to prevent precipitating Korsakoff psychosis.
- If there is concomitant B12 and folate deficiency, start vitamin B12 first to avoid precipitating subacute combined degeneration of the spinal cord (1).
- Consider obtaining prealbumin/albumin levels and a dietary consult for malnourished patients.
- Bariatric surgery patients will need lifelong vitamin supplementation; there are no consensus practice guidelines for supplement dosing regimens.

**Geriatric Considerations**

- Vitamin B12 deficiency exists in ~20% of patients age >60 years. Treat symptomatic or severe deficiency with an IM injection of cyanocobalamin 1,000 μg/day 3 times a week for 2 weeks. If there are neurologic symptoms, give the same dose of cyanocobalamin every other day for 3 weeks or until symptoms have resolved. To prevent recurrence or treat mild deficiency, use a regimen of oral vitamin B12 1,000 μg/day or an IM injection of vitamin B12 1,000 μg every month. Low-dose oral therapy with 50 to 150 μg/day may be considered for mild cases (1). High-dose (1,000 to 2,000 μg/day) oral treatment is as effective as monthly IM injections, but use caution if malabsorption or compliance issues (1)[C].
- >40% of elderly Americans are vitamin D deficient. Deficiency is defined as a serum 25-OH vitamin D level of <20 ng/mL.
- Treat vitamin D deficiency with weekly 50,000 IU of oral ergocalciferol for 8 weeks. Recommended daily supplementation in those age >70 years is 800 IU/day of vitamin D.

**Pediatric Considerations**

- Vitamin K deficiency increases bleeding risk.
  - Neonates may exhibit signs of vitamin K deficiency because they require 1 week of life to establish intestinal flora, which manufactures vitamin K.
  - Condition peaks 2 to 10 days after birth: bleeding from the umbilical stump and/or circumcision site, generalized bruising, and GI hemorrhage.
  - Infrequent in developed countries due to routine injection of newborns with vitamin K (1
mg)

- Vitamin D deficiency: Vitamin D supplementation (400 IU/day) is recommended for all infants starting in the first few days of life (5)[A].
- 600 IU/day of vitamin D is recommended for children >12 months and adults either through diet or supplementation (5).
- Morbidly obese and minority children are at increased risk for vitamin D deficiency.
- In children age >6 months in developing countries, vitamin A supplementation has been shown to decrease mortality.
- Vitamin deficiency is associated with developmental delay.

**Pregnancy Considerations**

All pregnant women and women of childbearing age considering pregnancy are strongly encouraged to take a multivitamin containing at least 0.4 mg folic acid daily to prevent neural tube defects (4)[A].

## ONGOING CARE

**DIET**

Vitamins are best used by the body from food intake. Supplements should be used where it is not feasible to ingest the recommended amount of a particular vitamin.

**PATIENT EDUCATION**

- In healthy adults, multivitamins have no value if dietary intake is adequate and may increase risk of some cancers.
- Drug–drug interactions may occur between vitamins and medications. Patients should report all supplements and medications to their health care provider.
- Risk of vitamin toxicity is most common with fat-soluble vitamins (A, D, E, K).

**PROGNOSIS**

Most vitamin deficiencies are fully reversible if treated without undue delay.

**COMPLICATIONS**

- Vitamin toxicities
- Liver failure (vitamins A, D, E, K)
- Desquamation of skin (vitamin A)
- Neuropathy (vitamin B₆)
- Kidney stones (vitamin C, vitamin D)
- Hypercoagulability (vitamin K)
- Pseudohyperparathyroidism (vitamin D)
- Masking of pernicious anemia (folic acid)

## REFERENCES

ADDITIONAL READING

CODES

ICD10
- E56.9 Vitamin deficiency, unspecified
- E56.0 Deficiency of vitamin E
- E55.9 Vitamin D deficiency, unspecified

CLINICAL PEARLS

- Obtain a thorough dietary history when assessing for potential vitamin deficiencies.
- Specifically ask patients about dietary supplement use.
- The USPSTF recommends against daily vitamin D supplementation of 400 IU or less to prevent fractures in community-dwelling postmenopausal women.
- All women planning or capable of pregnancy should take a daily supplement containing 0.4 to 0.8 mg of folic acid.
- All infants and children, including adolescents, should have a minimum daily intake of 400 IU of vitamin D beginning soon after birth.
VITILIGO
Sonia Rivera-Martinez, DO ● Karen Sheflin, DO

BASICS

DESCRIPTION
- An acquired depigmentation of the skin, which correlates with a loss of epidermal melanocytes. There are three clinical variants, each with subtypes.
- Localized: often in childhood, rapid onset then stabilizes. Involvement of hair is common early in the course; lacks associated autoimmune diseases
  - Focal: few lesions, random distribution
  - Segmental: Lesions occur within a dermatome (mostly trigeminal) or may follow Blaschko lines. Lesions usually stop abruptly at the midline.
  - Mucosal: only mucosal surfaces involved
- Generalized/nonsegmental (most common variant): progressive, with flares, commonly associated with autoimmunity. Common locations are acral, periorificial, and in sites sensitive to pressure/friction (Koebner phenomenon).
  - Vulgaris: most common subtype; scattered macules; often symmetric, wide distribution; mostly hands, axillae, and groin
  - Acrofacial: on distal extremities and face
  - Mixed: coexistence of above
- Universal: involves >80% of the body surface area (BSA). Most likely to have family history; comorbidities are common and associated with poorest quality-of-life (QOL) scores.
- Other rare variants
  - Ponctué: discrete, confetti-like macules
  - Inflammatory: peripheral erythematous rim
  - Trichrome: Tan zone is present between normal and depigmented skin.
  - Quadrichrome: as above but with marginal/perifollicular hyperpigmentation
  - Blue: Dermal melanophages give blue hue in areas affected by prior postinflammatory hyperpigmentation.
- System(s) affected: skin, mucous membranes
- Synonym(s): leukoderma

EPIDEMIOLOGY
- 50% begin before age 20 years, peak in females: 1st decade; males: 5th decade. Onset earlier with positive family history; can appear as early as 6 weeks
- Predominance: male = female; however, females are more likely to seek treatment.
- No race or socioeconomic predilection

Prevalence
~1% in the United States and Europe (1); 0.1–8% in the world; highest in Gujarat, India at 8.8% (1,2)

ETIOLOGY AND PATHOPHYSIOLOGY
Most likely a spectrum of disorders with a common phenotype and multiple mechanisms contribute to the pathology (convergence theory).
● Genetic: See “Genetics.”
● Autoimmune: humoral autoantibodies and skin-homing T cells
● Neural: local or systemic dysregulation leading to excess neurotransmitters
● Viral: direct melanocyte toxicity, cytomegalovirus (CMV), hepatitis C, and Epstein-Barr virus (EBV) found in lesional biopsies
● Oxidative stress from elevated H\textsubscript{2}O\textsubscript{2} and NO and decreased catalase and erythrocyte glutathione

**Genetics**
● Polygenic/multifactorial inheritance
● 20% of patients report affected relative, but monozygotic twins have only 23% concordance.
● HLA haplotypes, small nucleotide polymorphisms, and specific genes are all possible contributors.

**RISK FACTORS**
● Family history of vitiligo/autoimmune disorders
● Personal history of associated conditions

**COMMONLY ASSOCIATED CONDITIONS**
● Most common
  – Endocrine: thyroid disease (hypo-/hyperthyroidism), hypoparathyroidism, Addison disease, insulin-dependent diabetes
  – Dermatologic: psoriasis, atopic dermatitis, alopecia areata, chronic urticaria, halo nevi, ichthyosis
  – Pernicious anemia
  – Hypoacusis, rheumatoid arthritis
  – Ocular abnormalities in up to 40%
  – Elevated antinuclear antibodies in up to 40%
  – Elevated thyroperoxidase antibodies in 50%
● Less common
  – Systemic lupus erythematosus
  – Inflammatory bowel disease
  – Melanoma (may be a sign of positive outcome of melanoma) and other skin cancers
  – Syndromes: Alezzandrini; mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes (MELAS); Schmidt; and autoimmune polyendocrinopathy-candidiasis-ectodermal dystrophy (APECED)
● Age >50 years at onset should prompt investigation for associated conditions.

**Pediatric Considerations**
Associated with Hashimoto thyroiditis in a significant portion of children. Screening at onset and possibly annually may be beneficial.

**DIAGNOSIS**

**HISTORY**
● Inquire about recent history of sunburns, pregnancy, skin trauma, or emotional stress.
● Family history of premature graying, vitiligo, and autoimmune disorders
Review of systems for related associated conditions
Ascertain psychological impact on QOL, Dermatology Life Quality Index (DLQI).

**PHYSICAL EXAM**
- Full-body skin exam with Wood lamp to accentuate lesions and distinguish depigmentation from hypopigmentation
- Lesions are well-demarcated, uniform, white macules and patches.
- Look for evidence of repigmentation (most commonly around hair follicles).

**DIFFERENTIAL DIAGNOSIS**
- Infectious: tinea versicolor, leprosy, leishmaniasis, onchocerciasis, treponematoses (pinta/syphilis)
- Postinflammatory hypopigmentation: psoriasis, atopic dermatitis, pityriasis alba, systemic lupus erythematosus, scleroderma
- Inherited hypomelanoses: piebaldism, tuberous sclerosis, Waardenburg, hypomelanosis of Ito, Vogt-Koyanagi-Harada
- Malformations: nevus anemicus, nevus depigmentosus
- Paraneoplastic: mycosis fungoides, melanoma-associated leukoderma
- Occupational and chemical induced
  - Occupational: phenolic/catechol derivatives and arsenic-containing compounds
  - Chemical: numerous, including cosmetics, cleansers, insecticides, and even medications (imatinib, potent topical corticosteroids [TCS])
- Melasma: Normal skin may be confused as vitiligo in the setting of surrounding hyperpigmentation.
- Halo nevi
- Lichen sclerosus et atrophicus
- Idiopathic guttate hypomelanosis
- Progressive-acquired macular hypomelanosis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- TSH, CBC, ANA
- Consider antithyroid peroxidase, antithyroglobulin antibodies, hemoglobin, vitamin B₁₂ levels if family/patient history of autoimmune disease.

**Follow-Up Tests & Special Considerations**
- Monitor for disease progression/flares.
- Monitor for symptoms of related conditions.

**Diagnostic Procedures/Other**
- Skin biopsy is rarely needed. Highest yield is with comparison of lesional/perilesional biopsies.
- Consider ophthalmologic and audiologic evaluation.

**Test Interpretation**
Few or no epidermal melanocytes. At margins, melanocytes may be larger, vacuolated, and dendritic. Early lesions show inflammation and later, degeneration, including of adnexa and nerves.
TREATMENT

The variant of vitiligo may affect response.
- If untreated, progression is the natural course for those with mucosal involvement, family history, koebnerization, and nonsegmental variants.
- Lesions that respond best are on the face, of recent onset, in darker skin type, and in younger patients.

GENERAL MEASURES
- Sunscreen to decrease sunburn and prevent accentuation of uninvolved skin
- Corrective camouflage as cover-up (Cover FX, Dermablend)

MEDICATION
- Individualize therapy depending on age, extent, distribution, and rate of progression.
- Many therapies are considered “off-label” and not FDA-approved for vitiligo, although they are often considered first-line therapy.
- Corticosteroids: Midpotency TCS (mometasone furoate, fluticasone propionate) applied daily as monotherapy are considered first-line treatments. Do not use on face/axilla/groin; do not occlude except under close monitoring. Pediatric: as above, for children >12 years of age. Consider decreased potency. Local side effects including atrophy, telangiectasia, hypertrichosis, acneiform eruptions, and striae limit treatment; regular steroid holidays are recommended (1). The combination of light therapy and TCS is the most effective treatment overall (2). Most efficacious on sun-exposed areas: face/neck, dark-skinned patients, newer lesion (1). Addition of tretinoin 0.025–0.05% BID is effective and can decrease potential skin atrophy (2,3). Systemic corticosteroids can be helpful, but dosage and safety parameters have not been fully evaluated for long-term treatment (2,4)[A].
- Topical calcineurin inhibitors: slightly inferior to TCS as monotherapy but better side effect profile (2,5,6)[B]; can be used as adjunctive to light therapy; carries a controversial black box warning for a theoretical risk of lymphoma or skin cancer. Extensive safety profiling has not revealed any evidence for this in children or adults using topical calcineurin inhibitors. Local reactions include burning sensation, pruritus, erythema, and rare transient hyperpigmentation (4).
  - Tacrolimus 0.03% or 0.1% ointment BID (2); pediatric: 0.03% ointment BID, for children >2 years of age (6)
  - Pimecrolimus 1% cream BID (2); pediatric: as adults, for children >2 years of age (6)
- Topical vitamin D₃ analogs: less effective than TCS alone but in combination with TCS or phototherapy can shorten time until, and improve stability of, repigmentation (4,5)[B]
  - Calcipotriene ointment 1 to 2 times per day; pediatric: not defined
  - Available as a combination formulation, betamethasone dipropionate 0.064%/calcipotriene 0.005% ointment daily, max dose of 100 g/week for 4 weeks, not for >30% BSA, and not for face/axilla/groin; pediatric: not defined
- Oral vitamin D₃: reported to induce repigmentation. Oral vitamin D₃ 35,000 IU once daily plus low-calcium diet for 6 months; pediatric: not defined
- Phototherapy: Narrow band UVB (NBUVB) is superior to UVA and indicated for lesions involving >15–20% BSA (3,5,6)[A]. Psoralen and khellin enhance the effect of light. Psoralen plus UVA (PUVA) may increase the incidence of skin cancers. Khellin may have reduced
cross-linking of DNA and may be less carcinogenic; however, it is associated with increased liver toxicity (6). L-phenylalanine can be used topically and orally as a photosensitizer for natural or artificial light. Pediatric: Oral PUVA is contraindicated.

- Laser therapy: Excimer laser (308 nm) is superior to other light therapy. Helium–neon laser works for segmental vitiligo (5)[A].
- Antioxidants: may have protective role in preventing melanocyte degradation from reactive oxygen species. Options include vitamin C, vitamin E, Vitix, Polypodium leucotomos extracts, and Ginkgo biloba (5)[B].
- Surgical therapy: See later discussion.
- New concepts: Tumor necrosis factor-α inhibitors, cyclosporine, cyclophosphamide, azathioprine, minocycline, and immunosuppressants are currently being evaluated (6).

First Line
- Recommended: avoidance of triggering factors plus TCS alone or in combination with NBUVB
- Alternatively
  - Topical calcineurin inhibitors (preferred for face, neck, axilla, and groin)
  - NBUVB
  - PUVA in adults
  - Camouflage and psychotherapy should be offered to all patients at any stage (6).

Second Line
- Recommended: photochemotherapy with psoralens or vitamin D analogues
- Alternatively
  - Topical vitamin D analogues
  - Targeted phototherapy
  - 308-nm laser in combination with topical steroids, topical calcineurin inhibitors, or vitamin D analogues
  - Oral corticosteroids (pulse therapy)
  - Surgical treatments indicated for stable 2- to 3-cm lesions, refractory to other treatments
    - Mini-punch graft (pretreat with cryotherapy/dermabrasion or posttreat with phototherapy) (6)[B]
    - Suction blister graft (6)[B]
    - Autologous melanocyte suspension transplant (5)[B]

ISSUES FOR REFERRAL
- Dermatologist: for facial/widespread vitiligo or when advanced therapy is necessary
- Ophthalmologist: for ocular symptoms or monitoring of TCS near eyes
- Endocrinologist: evaluation/management of associated conditions
- Psychologist: for severe distress
- Medical geneticist for associated conditions

ADDITIONAL THERAPIES
- Depigmentation therapy with monobenzone, hydroquinone, or Q-switched ruby laser: for extensive vitiligo recalcitrant to therapy (6)
- Pseudocatalase with addition of NBUVB (1)[B]
- Prostaglandin E for short-duration disease and localization to face and scalp (2)[B]
- Cosmetic tattooing for localized stable vitiligo
SURGERY/OTHER PROCEDURES
- Goal is to transport melanocytes from other areas of the skin. Methods include punch, blister, or split-thickness skin grafting, or transplantation of autologous melanocytes.
- Dermabrasion and curettage alone or in combination with 5-fluorouracil may induce follicular melanocyte reservoirs (5)[A].
- Patients who koebnerize or form keloids may be worse, and permanent scarring is a risk for all patients.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Ginkgo biloba 60 mg PO daily may significantly improve extension and spreading of lesions (4) [B].
- Polypodium leucotomos may help with repigmentation with NBUVB and aid in reducing phototoxic reactions (5)[B].

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- Monitor for symptoms of related conditions.
- With topical steroids, follow at regular intervals to avoid steroid atrophy, telangiectasia, and striae distensae.

DIET
No restrictions

PATIENT EDUCATION
- Discussion of disease course, progression, and cosmesis
- Education regarding trauma/friction and Koebner phenomenon

PROGNOSIS
- Vitiligo may remain stable or slowly or rapidly progress.
- Spontaneous repigmentation is uncommon.
- Generalized vitiligo is often progressive, with flares. Focal vitiligo often has rapid onset and then stabilizes.

COMPLICATIONS
- Adverse effects of each treatment modality
- Psychiatric morbidity: depression, adjustment disorder, low self-esteem, sexual dysfunction, and embarrassment in relationships (1,2)
  - Different cultures may have different perceptions/social stigmas about vitiligo. Some believe it to be contagious or related to infection. Women with vitiligo may have difficulty finding a marriage partner and have low self-esteem.

REFERENCES

ADDITIONAL READING

CODES

ICD10
L80 Vitiligo

CLINICAL PEARLS

- Vitiligo can be a psychologically devastating skin disease.
- Screen for associated diseases, particularly if onset occurs later in life.
- Treatment should be individualized based on BSA, skin type, and patient goals.
- Dermatology consultation when extensive disease, facial involvement, and when advanced treatments are considered
VON WILLEBRAND DISEASE
Diana Desai, MD, MBA

BASICS
DESCRIPTION
- von Willebrand disease (vWD) is an inherited bleeding disorder resulting from either a quantitative or qualitative defect in von Willebrand factor (vWF) protein.
- vWF plays an essential role in primary hemostasis, which facilitates the adherence of platelets to the injured blood vessel; it also serves as a carrier for factor VIII (FVIII) in the circulation.
- The most common clinical consequences of vWD are mucocutaneous bleeding, bleeding during childbirth and dental procedures, easy bruising, and menorrhagia (signs of platelet type bleeding). On the contrary, patients suffering from bleeding disorders caused by coagulation factor deficiencies or inhibitors typically experience hemarthroses.
- vWD is most commonly diagnosed as an inherited condition but rarely can be acquired (AvWD).

EPIDEMIOLOGY
Prevalence
- Prevalence of the inherited forms of vWD is 1 in 100 to 10,000 of the general population with more females being diagnosed than males.
- Exact prevalence of the acquired forms of vWD (AvWD) is unknown but is estimated to be up to 0.1% of the general population.

ETIOLOGY AND PATHOPHYSIOLOGY
- vWF is a large, multimeric glycoprotein that is released from endothelial cells and stored within the α-granules of platelets (1).
- vWF binds to subendothelial collagen at sites of vascular injury and facilitates platelet adhesion to these sites via its interaction with the platelet GP1b receptor. A platelet plug is formed, allowing for the initial arrest of bleeding (primary hemostasis). The formation of a fibrin clot follows the creating of the platelet plug, which requires normal amounts of and function of coagulation factors (secondary hemostasis).
- vWF acts as a carrier for FVIII in the circulation, protecting it from degradation. A deficiency in vWF may result in decreased FVIII levels.
- When vWF is deficient or dysfunctional, primary hemostasis is compromised, resulting in the clinical symptoms described above.
- There are three distinct types of inherited vWD. Within this classification scheme, type 2 vWD has several subtypes, described below (1). Whereas type 1 and type 3 are associated with quantitative deficiencies in vWF (decreased in type 1, absent in type 3), type 2 vWD results from functional defects in the glycoprotein.
  - Type 1, the most common and mildest form, represents 70–80% of cases.
  - Type 2, caused by qualitative defects in vWF, accounts for 10–15% of cases. The various subtypes are described below.
    - Type 2A results from the absence of high- and intermediate-molecular-weight multimers of vWF.
- Type 2B occurs due to a gain-of-function mutation in vWF, which increases its affinity for the platelet GP1b receptor. Complexes of platelet and vWF form as result, and are subsequently removed from the circulation. Removal of these aggregates results in loss of the high-molecular-weight multimers on vWF as well as thrombocytopenia.
- Type 2M results from a defect in the platelet binding domain of vWF, however, in contrast to types 2A and 2B, the entire vWF multimer remains intact.
- Type 2N results from a mutation in the factor VIII binding domain of vWF, resulting in low factor VIII levels with an intact multimer.
  - Type 3 represents 1–5% of cases, the least common and most severe form.
  - Most severe form with markedly decreased-to-undetectable levels of vWF and FVIII
- Platelet-type vWD (PLT-vWD), also known as pseudo-vWD, results from a hyperaffinity mutation in the platelet GP1b receptor, causing increased binding to vWF. Consequently, many platelet-vWF complexes form, which are then cleared from the circulation. Similar to vWD type 2B, these patients will demonstrate loss of high-molecular-weight multimers of vWF in addition to thrombocytopenia. Although the clinical profile and laboratory testing of these two disorders are often indistinguishable through routine testing, the underlying pathophysiology and treatment strategies widely differ.
- AvWD may be due to cardiovascular, hematologic, or autoimmune conditions as well as tumors and medications. The pathophysiology of AvWD is related to the underlying cause and may result from shear-induced cleaving of vWF in cardiovascular conditions, increased adsorption of vWF by certain tumor cells or activated platelets, or presence of anti-vWF autoantibodies in hematologic disorders.

**Genetics**
- The 175-kb gene for vWF is located on short arm of chromosome 12.
- Type 1 follows an autosomal-dominant inheritance pattern, with variable expressivity.
- Type 2 follows both autosomal-dominant and autosomal-recessive inheritance patterns.
- Type 3 follows an autosomal-recessive inheritance pattern.

**RISK FACTORS**
Personal and/or family history of bleeding disorder

**COMMONLY ASSOCIATED CONDITIONS**
- Individuals with type O blood have accelerated clearance of vWF leading to vWF levels that are 25–30% lower than other those with blood type A, B, or AB. Type 1 disease is diagnosed more frequently in individuals with type O blood.
- AvWD may be found in patients with hematologic disorders such as monoclonal gammopathy of undetermined significance and myeloproliferative neoplasms. Commonly associated cardiovascular conditions include aortic stenosis and left ventricular assist device (LVAD) placement. AvWD is associated with gastrointestinal (GI) bleeding from arteriovenous malformations.

**DIAGNOSIS**

**HISTORY**
- Most patients with vWD have a positive family history of a bleeding disorder; however, patients with mild forms of vWD and their families may be unaware of their disease. Those
with AvWD usually have no family history of this disorder.
- Common symptoms include mucocutaneous (recurrent epistaxis, menorrhagia, ecchymosis) or postprocedural bleeding.
- The most important component of diagnosis is the bleeding history, often aided by specifically designed bleeding questionnaires, such as the ISTH-BAT found at isth.org (International Society on Thrombosis and Haemostasis).
- American College of Obstetricians and Gynecologists recommends initial reproductive visits for girls between age 13 and 15 years. vWD should be in the differential for heavy menstrual bleeding, at any age, but especially adolescents, when bleeding disorders may be overlooked and incorrectly attributed to an immature hypothalamic–pituitary axis.

**PHYSICAL EXAM**
Physical exam may be entirely normal, but may demonstrate ecchymoses and/or petechiae.

**DIFFERENTIAL DIAGNOSIS**
Congenital thrombocytopenia, qualitative platelet defects, coagulation factor deficiencies, hemophilia, dysfibrinogenemias, fibrinolytic disorders, liver disease, uremia, connective tissue disorders, coagulation factor inhibitors

**DIAGNOSTIC TESTS & INTERPRETATION**
- Initial evaluation of a suspected bleeding abnormality (1)
  - Complete blood count (platelet count)
  - Prothrombin time
  - Partial thromboplastin time
  - Fibrinogen level
  - Peripheral blood smear
- Initial evaluation of suspected inherited vWD (1)[C]
  - vWF antigen (vWF:Ag): determines total amount of vWF present
  - vWF activity (vWF:RCo): functional assay tests vWF function by assessing its ability to agglutinate platelets in the presence of the antibiotic ristocetin
  - Factor VIII:C level
  - Of note, multimeric analysis is not recommended in the initial evaluation of vWD.

↓ refers to a decrease in the test result compared to the laboratory reference range.

* <30 IU/dL is designated as the level for a definitive diagnosis of vWD; some patients with type 1 or type 2 vWD have levels of vWF:RCo and/or vWF:Ag of 30–50 IU/dL.

† The vWF:Ag in the majority of individuals with type 2A, 2B, or 2M vWD is <50 IU/dL.

** This does not preclude the diagnosis of vWD in patients with vWF:RCo of 30–50 IU/dL if there is supporting clinical and/or family evidence for vWD, nor does this preclude the use of agents to increase vWF levels in those who have vWF:RCo of 30–50 IU/dL and who may be at risk for bleeding.

Notes:

Until more laboratories clearly define a reference range, the vWF:RCo/vWF:Ag ration of 0.5–0.7 is recommended to distinguish type 1 vWD vs. type 2 vWD variants (A, B, or M). Grade C, level IV. 30 IU/dL is recommended as the “cut-off” level for the definite diagnosis of vWD for the following reasons:

- There is a high frequency of blood type O in the United States, and it is associated with “low” vWF levels;
- Bleeding symptoms are reported by a significant proportion of individuals with no disease; and
- No abnormality in the vWF gene has been identified in many individuals who have mildly to moderately low vWF:RCo levels. Grade C, level IV.

- Interpretation of tests should always be preceded by significant bleeding history; best assessed with ISTH-BAT score and family history for bleeding and/or diagnosed with vWD.

Follow-Up Tests & Special Considerations

- Unless patients have severe forms of vWD or are undergoing treatment, follow-up laboratory studies are not usually obtained.

- vWF is an acute-phase reactant, so elevations may be seen in inflammatory conditions, liver disease, pregnancy (which may correct mild deficits), or with estrogen use. Levels also increase with age; however, it is unclear if this decreases bleeding risk.

** TREATMENT **

GENERAL MEASURES

- Minor bleeding episodes generally do not require therapeutic intervention. Most commonly, these individuals receive treatment prior to receiving surgeries, dental procedures, and following injury.

- In patients with mild disease, trauma-related and spontaneous bleeding events may be managed with desmopressin acetate (DDAVP), which releases endogenous vWF stored in the patient’s endothelial cells.

MEDICATION

First Line

- Desmopressin (DDAVP)
  
  - Enhances release of vWF from endothelial cells
  
  - Primarily effective for type 1 vWD; not indicated in type 2B. Trial of DDAVP should initially be measured in nonbleeding state to determine response.

  - Not effective in vWD type 3

  - Dosed 0.3 μg/kg (max 20 mg) IV/SC; intranasal (high concentration) spray: <50 kg: 150
μg/day; >50 kg: 300 μg/day (Stimate)

- Common side effects: flushing, tachycardia, water retention, hyponatremia. Tachyphylaxis may develop with prolonged dosing; limit use to administering DDAVP once every 24 to 48 hours for 3 to 5 days.
- Test therapeutic responsiveness by testing vWF:Ag, vWF:RCo, and FVIII:C at baseline, 1 hour and 4 hours postinfusion. An increase in levels at least 2- to 3-fold, >30 IU/dL and preferably >50 IU/dL for invasive procedures, is adequate response; vWF and FVIII concentrates

- Replacement therapy with vWF and/or factor VIII concentrates are the most effective treatment for patients with type 2 and type 3 vWD. However, in cases of PT-vWD, administration of exogenous platelets is the treatment of choice. Plasma-derived vWF and FVIII concentrates of various purity such as Humate-P and Alphanate are commercial preparations of vWF and FVIII that are given in doses of 25 to 60 IU/kg/day based on clinical condition.
  - Administration of 1 IU/kg vWF:RCo concentrate raises the plasma RCo activity by approximately 2%.
  - Dose of vWF concentrate may be adjusted for FVIII levels and ristocetin cofactor activity.
  - FVIII levels should be monitored to avoid supranormal levels and possible venous thromboembolism (VTE).
  - Contraindicated if patient develops alloantibodies to vWF
  - Recombinant vWF concentrate (Vonvendi) is approved for use in adults for on-demand treatment of bleeding episodes. It requires rFVIII with the first infusion if baseline levels are <40% or unknown.
  - In patients with severe bleeding phenotype, prophylactic treatment is used.
- Antifibrinolytics
  - Useful for mucosal bleeding
  - Contraindicated in patients with hematuria due to risk of retention of large blood clots in the renal collecting system
  - Given as adjunct to DDAVP
  - Aminocaproic acid may be given at 50 to 70 mg/kg (max: 5 g; lower doses may be effective) q4–6h IV or PO.
  - Tranexamic acid may be given at 10 to 15 mg/kg IV or 25 mg/kg (1,300 mg) PO q8–12h.
  - Recombinant FVIIa (NovoSeven)
    - Given as IV bolus of 90 μg/kg q2h or 20 μg/kg every hour until hemostasis is achieved
    - Used for patients who develop alloantibodies to vWF
    - Used effectively in the treatment of patients with type 3 vWD

**Second Line**

- Combined oral contraceptives or the levonorgestrel-releasing intrauterine system raise vWF/FVIII levels in the blood and also have a role in the treatment of chronic menorrhagia.
- Platelets may be given as an adjunct to factor concentrates if hemostasis has not been achieved.
- Intravenous immunoglobulin has been useful in some patients with AvWD associated with monoclonal gammopathy.

**ISSUES FOR REFERRAL**

Consider consultation with a hematologist.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patients should be seen by a hematologist prior to invasive procedures.

Patient Monitoring
Patients with mild disease do not require monitoring.

DIET
No dietary restrictions are recommended. However, aspirin and other NSAIDs should be avoided.

PATIENT EDUCATION
National Hemophilia Foundation:
https://www.hemophilia.org/NHFWeb/MainPgs/MainNHF.aspx?menuid=182&contentid=47&rptname=bleeding

PROGNOSIS
Patients with vWD have normal life expectancy.

COMPLICATIONS
- Significant perioperative bleeding may occur.
- Patients with type 3 vWD and type 2N can have bleeding complications similar to patients with hemophilia A, such as hemarthrosis and intracranial hemorrhage.
- Patients with aortic stenosis and AvWD are known to have higher rates of GI bleeding.
- Multiple transfusions may result in alloantibodies against vWF.
- Venous thromboembolism may result from supranormal levels of FVIII.

CODES
ICD10
D68.0 Von Willebrand’s disease

CLINICAL PEARLS
- vWD is the most common inherited bleeding disorder in American women, and its
manifestations vary from minor to severe bleeding episodes.
- Treatment should be administered for recurrent bleeding episodes in all types of vWD, but prophylaxis is not required for minor bleeding events.
VULVAR MALIGNANCY
Jessica C. Nazzaro, DO ● Michael P. Hopkins, MD, MEd

BASICS

DESCRIPTION

- Premalignant lesions of the vulva are collectively known as vulvar intraepithelial neoplasia (VIN).
- Exposure to human papillomavirus (HPV) has been linked to >70% of VIN.
- Invasive squamous cell carcinoma is the most common malignancy involving the vulva (90% of patients); can be well, moderately, or poorly differentiated and derives from keratinized skin covering the vulva and perineum.
- Melanoma is the second most common type of vulvar malignancy (8%) and sarcoma is the third.
- Other invasive cell types include basal cell carcinoma, Paget disease, adenocarcinoma arising from Bartholin gland or apocrine sweat glands, adenoid cystic carcinoma, small cell carcinoma, verrucous carcinoma, and sarcomas.
- Sarcomas are usually leiomyosarcoma and probably arise at the insertion of the round ligament in the labium majus; however, sarcoma can arise from any structure of the vulva, including blood vessels, skeletal muscle, and fat.
- Rarely, breast carcinoma has been reported in the vulva and is thought to arise from ectopic breast tissue.
- System(s) affected: reproductive

Geriatric Considerations

- Older patients with associated medical problems are at high risk from radical surgery. The surgery, however, is usually well tolerated.
- Patients who are not surgical candidates can be treated with combination chemotherapy and/or radiation.
- In the very elderly, palliative vulvectomies provide relief of symptoms for ulcerating symptomatic advanced disease.

EPIDEMIOLOGY

Incidence

- In 2015, 5,150 women were diagnosed with vulvar cancer and 1,080 women died from vulvar cancer in the United States; accounting for approximately 4% of all gynecologic malignancies.
- Estimated 6,020 new cases and 1,150 deaths in 2017.
- Surveillance, epidemiology, and end result (SEER) data showed that the incidence of in situ vulvar carcinoma increased by >400% between 1973 and 2000.
- Mean age at diagnosis 65 years; in situ disease: mean age 40 years; invasive malignancy: mean age 60 years.
- 30–35% of vulvar cancer cases are diagnosed at FIGO stages III and IV.
- Ethnic distribution: more common in Caucasian women than in any other race.

ETIOLOGY AND PATHOPHYSIOLOGY
Patients with cervical cancer are more likely to develop vulvar cancer later in life, secondary to “field effect” phenomenon with a carcinogen involving the lower genital tract.

HPV has been associated with squamous cell abnormalities of the cervix, vagina, and vulva; 55% of vulvar cancers are attributable to oncogenic HPV, predominantly HPV 16 and 33; vaginal intraepithelial neoplasia (VAIN) 2/3 and anal intraepithelial neoplasia (AIN) are attributable to HPV.

Squamous cell carcinoma
- There are two etiologic pathways for developing vulvar squamous cell carcinoma: lichen sclerosus and HPV.
- The International Society for the Study of Vulvovaginal Disease (ISSVD) proposed a revised terminology in 2015: low-grade squamous intraepithelial lesion (LSIL), which includes flat condyloma and HPV effect, high-grade squamous intraepithelial lesion (HSIL), and VIN differentiated type (dVIN). The ISSVD previously used a three level system grading VIN as 1, 2, 3, which has been abandoned.
- Differentiated type occurs in older age groups, is associated with lichen sclerosus and chronic venereal diseases, and is not related to HPV. It carries a higher risk of progression to malignancy.

The warty basaloid type, also known as bowenoid type, is related to HPV infection and occurs in younger women. Melanoma, second most common histology, often identified in postmenopausal women; often pigmented but can be amelanotic, arising de novo, often found on clitoris or labia minora. Prognosis is poor, 5-year survival <50%.

Smoking is associated with squamous cell disease of the vulva, possibly from direct irritation of the vulva by the transfer of tars and nicotine on the patient’s hands or from systemic absorption of carcinogen.

Genetics
No known genetic pattern

RISK FACTORS
- VIN or cervical intraepithelial neoplasia (CIN)
- Smoking
- Lichen sclerosus (vulvar dystrophy)
- HPV infection, condylomata, or sexually transmitted diseases (STD) in the past
- Low economic status
- Autoimmune processes
- Immunodeficiency syndromes or immunosuppression
- Northern European ancestry
- Risk factors for recurrence: age >50 years, positive excision margins, concurrent VAIN

GENERAL PREVENTION
- HPV vaccination has the potential to decrease vulvar cancer by 60%.
- Abstinence from smoking/smoking cessation counseling

COMMONLY ASSOCIATED CONDITIONS
- Patients with invasive vulvar cancer are often elderly and have associated medical conditions.
- High rate of other gynecologic malignancies
DIAGNOSIS

HISTORY
Complaints of pruritus or raised lesion in the vaginal area, vaginal bleeding, discharge

PHYSICAL EXAM
- In situ disease: a small raised area associated with pruritus, single vulvar plaque, ulcer, or mass on labia majora, perineum, clitoris; most commonly found on labia majora
- Vulvar bleeding, dysuria, enlarged lymph nodes less common symptomatology
- Invasive malignancy: an ulcerated, nonhealing area; as lesions become large, bleeding occurs with associated pain and foul-smelling discharge; enlarged inguinal lymph nodes indicative of advanced disease

DIFFERENTIAL DIAGNOSIS
- Infectious processes can present as ulcerative lesions and include syphilis, lymphogranuloma venereum, and granuloma inguinale.
- Disorder of Bartholin gland, seborrheic keratosis, hidradenomas, lichen sclerosus, epidermal inclusion cysts
- Crohn disease can present as an ulcerative area on the vulva.
- Rarely, lesions can metastasize to the vulva.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Hypercalcemia can occur when metastatic disease is present.
- Squamous cell antigen can be elevated with invasive disease.

Follow-Up Tests & Special Considerations
- Upon examination, any suspicious lesions should be biopsied.
- Diagnosis based on histologic findings following vulvar biopsy (2)
- The vulva can be washed with 3% acetic acid to highlight areas and visualized with a colposcope, allows for visualization of acetowhite lesions and vascular lesions (2).
- For patients with new onset of pruritus, the area of pruritus should be biopsied.
- Liberal biopsies must be used to diagnose in situ disease prior to invasion and to diagnose early invasive disease.
- The patient should not be treated for presumed benign conditions of the vulva without full exam and biopsy, including Pap smear and colposcopy of cervix, vagina, and vulva.
- When symptoms persist, reexamine and rebiopsy.
- Treatment of benign condyloma of the vulva has not been shown to decrease the eventual incidence of in situ or invasive disease of the vulva.
- CT scan to evaluate pelvic and periaortic lymph node status if tumor >2 cm or if suspicion of metastatic disease (2)[A]

Diagnostic Procedures/Other
Office vulvar biopsy is done to establish the diagnosis.

Test Interpretation
A surgical staging system is used for vulvar cancer (International Federation of Obstetrics and Gynecology Classification).
Stage I: tumor confined to the vulva
  – Stage IA: lesions ≤2 cm in size, confined to the vulva or perineum and with stromal invasion ≤1 mm, no node metastasis
  – Stage IB: lesions >2 cm in size or with stromal invasion >1 mm, confined to the vulva or perineum, with negative nodes
Stage II: tumor of any size with extension to adjacent perineal structures (lower 1/3 urethra, lower 1/3 vagina, anus) with negative nodes
Stage III: tumor of any size with or without extension to adjacent perineal structures (lower 1/3 urethra, lower 1/3 vagina, anus) with positive inguinofemoral lymph nodes
  – Stage IIIA
    – With 1 lymph node metastasis (≥5 mm), or
    – 1 to 2 lymph node metastases (<5 mm)
  – Stage IIIB
    – With ≥2 lymph node metastases (≥5 mm), or
    – ≥3 lymph node metastases (<5 mm)
  – Stage IIIC: with positive nodes with extracapsular spread
Stage IV: Tumor invades other regional (upper 2/3 urethra, upper 2/3 vagina) or distant structures.
  – Stage IVA: Tumor invades any of the following:
    – Upper urethral and/or vaginal mucosa, bladder mucosa, rectal mucosa, or fixed to pelvic bone
    – Fixed or ulcerated inguinofemoral lymph nodes
  – Stage IVB: any distant metastasis, including pelvic lymph nodes

TREATMENT

GENERAL MEASURES
  – Wide excision can be performed for carcinoma in situ, and any suspicious lesion should be excised for definitive diagnosis.
  – Cystoscopy and sigmoidoscopy should be performed if there is a question of invasion into the urethra, bladder, or rectum.

MEDICATION
  – Neoadjuvant therapy is being investigated with bleomycin-cisplatin and paclitaxel-based regimens showing high-response rates and tolerable side effects (3)[A].
  – As an adjuvant therapy, fluorouracil (Efudex) cream for in situ disease can produce occasional results but is not well tolerated because of irritation of the vulva (4)[A].
  – Chemoradiotherapy with cisplatin and 5-fluorouracil (5-FU) has been successful in advanced or recurrent disease, although local morbidity is increased (4)[A].
  – Contraindications: elderly patients: If chemotherapeutic agents are used, pay close attention to the patient’s performance status and ability to tolerate aggressive chemotherapy.

ISSUES FOR REFERRAL
Patients may need care from a gynecologic oncologist and/or a radiation oncologist.

ADDITIONAL THERAPIES
Preoperative radiation therapy can be used in those with advanced vulvar cancer (2)[B]. Adjuvant radiation should be considered with tumor size >4 cm, evidence of lymphovascular invasion, positive surgical margins, or lymph node involvement.

Preoperative chemoradiation allows for a less radical surgical procedure in patients who are not surgical candidates (4)[A]. Postoperative radiation decreases recurrence frequency and may improve survival (4)[A]. Radiation is contraindicated with verrucous carcinoma because it induces anaplastic transformation and increases metastases.

**SURGERY/OTHER PROCEDURES**

- In situ disease can be treated with wide excision or laser vaporization of the affected area. Laser vaporization is preferable in the younger patient, whereas wide excision is preferable in the elderly patient, in whom the risk of invasive disease is also higher (2)[A].
- If tumor extension within <1 cm from structures that will not be removed, preoperative radiation to prevent inadequate surgical margins prior to excision 1-cm tumor-free margin is required because smaller margin would increase risk of recurrence (4)[A].
- Inguinofemoral lymphadenectomy: removal of superficial inguinal and deep femoral lymph nodes.
- Targeted dissection of grossly involved nodes, termed nodal debulking, is being investigated due to high rates of complication after full inguinofemoral lymphadenectomy.
- Stage IA: radical local excision without lymph node dissection.
- Stage IB: radical local excision with either sentinel lymph node biopsy (SLNB) or ipsilateral inguinofemoral lymph node dissection because the risk of metastases is >8%.
- Stage II: modified radical vulvectomy and/or chemoradiation and groin node dissection.
- Stages III and IV: neoadjuvant chemoradiation and less radical surgery.
- Pelvic exenteration after radiation provides effective therapy for advanced or recurrent malignancies involving the bladder or rectum.
- More limited surgery has been undertaken for early invasive lesions, especially in young patients, to preserve the clitoris and sexual function.
- SLNB also has been advocated for early invasive lesion (stage IB or higher). It has shown to accurately diagnose groin metastases in women with early vulval cancer and unknown groin node status. This will limit the surgical morbidity associated with inguinofemoral lymphadenectomy in those with early stage disease.
- Radical vulvectomy with bilateral groin node dissection through separate incisions provides better cosmetic results than en bloc technique.
- Unilateral lymphadenectomy should be considered when lesion <2 cm, lateral lesion >2 cm from vulvar midline, or no palpable groin nodes.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Typically inpatient for treatment.
- Concurrent chemotherapy with radiation is considered standard of care if the patient can tolerate it, based on extrapolation from squamous cell cancers of the cervix and anus (4)[B].
- In advanced malignancy involving the urethra and rectum, concomitant cisplatin/5-FU chemotherapy with radiation produces a significant decrease in size of the primary tumor, usually obviating the need for pelvic exenteration.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Early stage, treated with surgery alone: clinical exam of the groin nodes and vulvar area every 6 months for 2 years and then annually
- Following chemoradiation, assessment for further treatment within 6 to 12 weeks of therapy completion
- Advance stage, clinical exam of the groin nodes and vulvar area every 3 months for 2 years, then every 6 months for 3 years, and then annually
- Cervical and/or vaginal cytology annually
- Majority of relapses occur within 1st year.

DIET
As tolerated and according to comorbid conditions

PATIENT EDUCATION
- American College of Obstetricians and Gynecologists (ACOG), 409 12th St. SW, Washington, DC 20024-2188; (800) 762-ACOG; http://www.acog.org/
- American Cancer Society: http://www.cancer.org/

PROGNOSIS
The 5-year survival is based on stage:
- Stage I: 78.5%
- Stage II: 58.8%
- Stage III: 43.2%
- Stage IV: 13.0%
- Inguinal and/or femoral node involvement is the most important determinant of survival.

COMPLICATIONS
- The major complications from radical vulvectomy and groin node dissection are wound breakdown, lymphedema, urinary stress incontinence, and psychosexual consequences.
- In the immediate postoperative period, ~50% of patients experience breakdown of the wound. This requires aggressive wound care by visiting nurses as often as twice a day. The wounds usually granulate and heal over a period of 6 to 10 weeks.
- ~15–20% of patients experience some form of mild to moderate lymphedema after the groin node dissection. These patients should be instructed in the use of leg elevation and support hose. <1% of patients experience severe, debilitating lymphedema.

REFERENCES

ADDITIONAL READING

CODES

ICD10

- C51.9 Malignant neoplasm of vulva, unspecified
- D07.1 Carcinoma in situ of vulva
- C51.0 Malignant neoplasm of labium majus

CLINICAL PEARLS

- 55% of vulvar cancers are attributable to oncogenic HPV. VAIN 2/3 and AIN are attributable to HPV. Therefore, HPV vaccination has the potential to decrease vulvar cancer by 1/3.
- Biopsy all suspicious or nonhealing vulvar lesions.
BASICS

DESCRIPTION

- Vulvar pain lasting 3 months or more; occurs in the absence of relevant visible findings, relevant lab abnormalities, or a clinically identifiable neurologic disorder.
- 2015 ISSVD (International Society for the Study of Vulvovaginal Disease) classification is based on whether vulvar pain is caused by a specific disorder or has no clear identifiable cause (1).
- Specific disorders (differential diagnosis) include infectious, inflammatory, neoplastic, neurologic, trauma, iatrogenic, or hormonal deficiency.
- Descriptors for unclear etiology include localized versus generalized versus mixed, provoked versus spontaneous versus mixed, primary versus secondary onset, and temporal.

EPIDEMIOLOGY

- Can occur at any age, but most women diagnosed between age 20 and 40 years (2).
- Nearly half of women opt not to seek treatment (3).
- Patients are psychologically comparable with asymptomatic controls and have similar marital satisfaction, but poorer overall sexual satisfaction.

Incidence

- Recent retrospective study estimates annual rate of new onset vulvodynia to be 1.8%.
- Evidence indicates lifetime cumulative incidence approaches 15%, suggesting nearly 14 million U.S. women will experience persistent vulvar discomfort at some point in their lives (4).

Prevalence

- Reports between 8.3% and 16%; non–clinical-based studies approximate a prevalence of 7% with validation by exam (3).
- Studies show Hispanics are 80% more likely to present with vulvar pain compared with Caucasians and African Americans.

ETIOLOGY AND PATHOPHYSIOLOGY

- Vulvodynia is likely neuropathically mediated:
  - Hypothesized that neurogenic inflammation sensitizes afferent nerves, and transmits impulses to the central nervous system (CNS), where reinforcing signals sustain pain loop.
  - In recent investigations of vulvar biopsy specimens, increased neuronal proliferation and branching in vulvar tissue are evident when compared with tissue of asymptomatic women.
- Pelvic floor pathology also should be considered: In one study, the vulvodynia group showed an increase in pelvic floor hypertonicity at the superficial muscle layer, less vaginal muscle strength with contraction, and decreased relaxation of pelvic floor muscles after contraction (4).
- No cause of vulvodynia has been established. It is most likely a neuropathic pain caused by a combination of the following:
- Recurrent vulvovaginal candidiasis or other infections
- Immune-mediated chronic neuroinflammatory process within vulvar tissues
- Chemical exposure (trichloroacetic acid) or physical trauma
- Reduced estrogen receptor expression/changes in estrogen concentration
- CNS etiology, similar to other regional pain syndromes

Genetics
Proposed genetic deficiency impairing one’s ability to stop the inflammatory response triggered by infection or chemicals; homozygosity of the two alleles of the interleukin (IL)-1 receptor antagonist occurs in 25–50% of vestibulodynia patients, compared with <10% in controls.

RISK FACTORS
- Vulvovaginal infections, specifically candidiasis. Unclear if infection, treatment, or underlying hypersensitivity is the cause (3). Multiple infections compound this risk.
- Hormonal factors: Controversial evidence proposes increased risk with use of oral contraceptive pills (OCPs); pain onset or increased severity may be associated with menopause. Symptoms may flare before menses.
- Pelvic floor dysfunction: Increased instability of pelvic floor muscles may perpetuate vulvar tissue inflammation, leading to vascular changes and histamine release.
- Comorbid interstitial cystitis and painful bladder syndrome; potentially related to common embryologic origin of structures
- Abuse: increased risk of vulvodynia if childhood had physical or sexual abuse by a primary family member; causal relationship remains unclear (4).
- Depression and anxiety (3)
- Other neuropathic and chronic pain disorders, including regional pain syndrome

GENERAL PREVENTION
- Wear 100% cotton underwear in the daytime and no underwear to sleep.
- Avoid douching and other vulvar irritants such as perfumes, dyes, and detergents.
- Avoid abrasive activities and tight, synthetic clothing.
- Avoid panty liners.
- Clean the vulva with water only and pat area dry after bathing.
- Avoid use of hair dryers in the vulvar area.

COMMONLY ASSOCIATED CONDITIONS
Higher incidence of chronic pain syndromes associated with vulvodynia, including chronic cystitis, irritable bowel syndrome, fibromyalgia, migraines, depression, endometriosis, low back pain. Women with vulvodynia have a higher incidence of depression and anxiety both preceding and resulting from their symptoms (3).

DIAGNOSIS
- Vulvodynia is a clinical diagnosis and it should be suspected in any women with chronic pain at the introitus and vulva.
- Pain should be characterized using a standard measure such as the McGill Pain Questionnaire; duration and nature of the pain should be established.
- Use physical exam to rule out other causes of vulvovaginal pain. Negative fungal culture,
along with relevant history and positive cotton swab test, confirms diagnosis.

**HISTORY**
Adequate sexual, social, and pain history should be taken to assess degree of symptoms. Visual pain scales and pain diaries may be helpful (5)[B]:
- Onset of vulvodynia often sudden and without precedents
- Pain often described as generalized, unprovoked
- Quality of pain is burning, stinging, irritating, or rawness (3).
- Specifically ask about bowel and bladder habits, history of trauma or abuse, history of infections including herpes and personal hygiene.
- Specific skin complaints may suggest alternate diagnosis; a history of allergies may suggest vulvar dermatitis.
- Assess for precipitants of vulvar pain: tight garments, bicycle riding, tampon use, prolonged sitting, perfumed or deodorant soaps, douching (3).
- Assess for complaints of dyspareunia:
  - Presence of vaginismus (involuntary vaginal muscle spasm), adequate lubrication, anorgasmia, partner problems, abuse
  - Psychosexual morbidity significantly higher in patients with vulvodynia; counseling may complement medical interventions.

**PHYSICAL EXAM**
- Ask patient to show where pain is localized or most painful.
- Mouth and skin exams to assess for lesions suggestive of lichen planus or lichen sclerosus
- Vaginal exam should be done to exclude other causes of vulvovaginal pain, including external inspection; palpation; and single digit, speculum, and bimanual exams:
  - The vulva may be erythematous, especially at the vestibule. Discomfort with separation of the labia minora is common.
  - Spontaneous or elicited pain at the lower 1/2 of anterior vaginal wall suggests bladder etiology.
- Bulbocavernosus and anal wink reflexes should be checked to assess for peripheral neuropathy.

**DIFFERENTIAL DIAGNOSIS**
- Infections: candidiasis, herpes, human papillomavirus (HPV), bacterial vaginosis, trichomoniasis, dermatophytes
- Inflammation: lichen planus, immunobullous disorder, allergic vulvitis, lichen sclerosus, atrophic vaginitis
- Neoplasia: Paget disease, vulvar or vaginal intraepithelial neoplasia, squamous cell carcinoma
- Neurologic/muscular: herpes neuralgia, spinal nerve compression, vaginismus

**DIAGNOSTIC TESTS & INTERPRETATION**
- Tampon test: reproduces pain in real-life settings
- Cotton swab or Q-tip test: Vulva tested for localized areas of pain, beginning at thighs and continuing medially toward vestibule, using the soft end and broken sharp end of the cotton swab. Five distinct positions (2, 4, 6, 8, and 10 o’clock) surveyed using light palpation. Pain rated on a scale from 0 (none) to 10 (most severe); posterior introitus and posterior hymenal remnants most common sites of increased sensitivity
- Test for concurrent vaginismus: Apply pressure with a gloved finger to levator ani and
obturator internus muscles to assess for tenderness, pain, or contracture.

**Initial Tests (lab, imaging)**
- Vaginal pH, wet mount, and yeast culture are recommended to rule out vaginitis.
- Gonorrhea and chlamydia testing done at physician’s discretion
- HPV screening is unnecessary; association is controversial between HPV and vulvodynia.

**Follow-up Tests & Special Considerations**
- Varicella-zoster and herpes simplex virus should be considered if ulcers or vesicular eruptions are present.
- Consider biopsy if concerned for neoplasm or dermatophyte infection or if the patient is resistant to treatment.

**Diagnostic Procedures/Other**
Colposcopy can be helpful if epidermal abnormalities are present. This should be done with caution because acetic acid worsens vulvar pain.

**Test Interpretation**
No specific histologic features are associated with vulvodynia, although reactive squamous atypia has been observed. Biopsies are unnecessary for diagnosis. Presence of rash/altered mucosa is not consistent with vulvodynia; this requires further evaluation (5)[C].

---

**TREATMENT**

Treatment is mostly based on expert opinion; high-quality research is limited by lack of standardized treatment outcome measures (6). Some experts prioritize non-pharmacologic therapies as evidence is stronger. For pharmacologic treatment, a trial of several medications for at least 3 months is usually needed to see effect.

**GENERAL MEASURES**
Combining treatments should be encouraged when treating women with vulvodynia (5)[C]; various reports on use of a combination of medical treatments, and psychotherapy, reveal women on these combinations do significantly better compared with those who receive medication only.

**MEDICATION**
- Oral therapies
  - Tricyclic antidepressants (TCAs): first-line treatment for unprovoked vulvodynia (5)[B]; do not stop use abruptly; contraindicated in patients with cardiac abnormalities and those taking MAOIs; fatigue, constipation, sweating, palpitations, and weight gain are most common side effects.
    - Amitriptyline, nortriptyline: most widely studied; start at 10 mg daily; dose titrated to pain control. Average effective dose is 60 mg daily. In one study, a 47% complete response rate was recorded (7)[B]. Nortriptyline may be preferred due to less anticholinergic adverse effects.
  - Anticonvulsant therapies:
    - Gabapentin: started at 300 mg daily at HS and increased by 300 mg every 3 days. Maximum recommended dose is 3,600 mg daily divided into 3 doses. 2018 randomized
controlled trial showed no improvement in tampon test pain compared to placebo.

- Topiramate and lamotrigine have been recommended if other therapies are not effective.
- Selective serotonin reuptake inhibitor-serotonin norepinephrine reuptake inhibitors: not commonly used; but there is some benefit for generalized vulvodynia (6) and can be helpful in those who cannot tolerate TCAs.
- Opioids/nonsteroidal anti-inflammatory drugs: not consistently helpful in relieving vulvar pain; not appropriate for maintenance

- Topical therapies
  - Generally, these are preferred in those with provoked vulvodynia (6).
  - A trial of local anesthetics may be recommended for all patients who present with vulvodynia. Use judiciously to avoid increased irritation (5)[C].
  - Lidocaine 5% ointment: for provoked vestibulodynia; application advised 15 to 20 minutes prior to intercourse. Penile numbness and possible toxicity with ingestion can occur.
    - In one study, lidocaine 5% ointment was left in vestibule overnight (average of 8 hours) for a period of 6 to 8 weeks; at follow-up, up to 76% of women reported no discomfort with intercourse (4)[C].
  - Cromolyn 4% cream: decreases mast cell degranulation in vulvar tissue; recommended application TID (3)[C]
  - Capsaicin 0.025%: decreases in discomfort and increases in frequency of intercourse with 20-minute daily application (4)[B]
  - Topical amitriptyline 2% combined with baclofen 2% is helpful in patients with comorbid vaginismus.
  - Topical corticosteroids and testosterone creams have not been shown to alleviate symptoms of vulvodynia.
  - Gabapentin 3–6% ointment (must be compounded)
  - Topical nitroglycerin may be helpful but may cause headaches.
  - Topical estrogen

- Injectable therapies
  - Triamcinolone acetonide: maximum of 40 mg should be injected monthly; is best when combined with 0.25–0.50% bupivacaine
    - Submucosal methylprednisone and lidocaine: reports of up to 68% response rate with weekly injections (5)[B]
    - Interferon-α: useful in treatment of vestibulodynia. Side effects (myalgias, fever, malaise) limit its use.
    - Botulinum toxin A injectable is being studied.

**ISSUES FOR REFERRAL**
A team approach is recommended for most effective management. Referral to psychosexual medicine, psychology, partner therapy, and pain management teams should be strongly considered (5)[B].

**ADDITIONAL THERAPIES**
- Cognitive-behavioral therapy (CBT): One randomized trial revealed that CBT is associated with a 30% decrease in vulvar discomfort with sexual intercourse. CBT is the recommended treatment for patients who present with dyspareunia as a main complaint (8)[B].
- Biofeedback/pelvic floor physical therapy: useful with concomitant vaginismus. Treats both generalized and localized vulvar pain; treatment value for unprovoked pain remains unclear.
Most studies report an average of 12- to 16-week treatment time.

- Vaginal dilators
- Surface electromyography (sEMG): effective for pelvic floor rehabilitation. Patients are more likely to experience pain-free sexual intercourse after sEMG; significant reductions seen on pain measures at long-term follow-up

**SURGERY/OTHER PROCEDURES**

- Surgery may be considered for patients with localized/provoked symptoms who have failed to respond to other measures; not recommended for generalized vulvodynia (5)[B]
- 60–80% of women who undergo surgery report a significant reduction in pain symptoms; however, when surveyed, patients prefer behavioral therapies than surgical intervention.
- All patients who are considering surgical intervention should be tested and treated for vaginismus. Vestibulectomy is less successful in this subgroup, and also in those with generalized symptoms (6).
- Surgical approaches
  - Local excision: precise localization of painful areas; tissue closed in elliptical fashion
  - Total vestibulectomy: Tissue is removed from Skene ducts to perineum. The vagina is then brought down to cover defect.
  - Perineoplasty: vestibulectomy plus removal of perineal tissue; incision usually terminated above the anal orifice; reserved for severe cases (3)[B]

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

Acupuncture: Small studies of women with unprovoked vulvodynia who did not respond to conventional treatment reported significant decreases in pain severity with acupuncture; treatment value with provoked pain is unknown (5)[C].

**ONGOING CARE**

**PATIENT EDUCATION**

Patients should be reassured that this condition is neither infectious, nor does it predispose to cancer (5)[C]. Counsel that condition is manageable, but likely not curable, and may require multiple therapeutic trials before remission is achieved. Emphasize self-hygiene. Encourage treatment with home remedies, including ice packs, sitz baths with baking soda, olive oil, and barrier cream to preserve moisture after bathing.

**PROGNOSIS**

Traditionally viewed as a chronic pain disorder, new evidence of remission has been documented; recent 2-year follow-up study revealed 1 in 10 vulvodynia patients reported remission regardless of treatment.

ADDITIONAL READING

CODES
ICD10
- N94.819 Vulvodynia, unspecified
- N94.818 Other vulvodynia
- N94.810 Vulvar vestibulitis

CLINICAL PEARLS
- Vulvodynia is a clinical diagnosis; it should be suspected in any woman with chronic pain at the introitus and vulva.
- A decrease in pain may take weeks to months and may not be complete.
- No single treatment is proven in all women; improvement over time is common even without treatment.
VULVOVAGINITIS, ESTROGEN DEFICIENT
Karla M. Alba, MD  •  Michelle Rodriguez, MD  •  Mark T. Nadeau, MD, MBA

BASICS

DESCRIPTION
- Estrogen-deficient vulvovaginitis is a hypoestrogenic state with external genital, urologic, and sexual sequelae.
- Estrogen deficiency affects all tissues in the female body; however, the genital tissues are especially hormone responsive and are most affected.
- Decreased estrogen leads to decreased blood flow to vaginal tissues and thinning of vaginal tissues, dryness, and atrophy. Patients with estrogen-deficient vulvovaginitis may present with urinary incontinence, vaginal burning and itching, dyspareunia, increased urinary frequency, recurrent UTIs, or various other symptoms.
- This condition is also referred to as genitourinary syndrome of menopause when associated with the postmenopausal state, although this condition may occur in women of all ages.
- System(s) affected: reproductive

EPIDEMIOLOGY

Incidence
Predominant age: postmenopausal females. The average age of menopause in the United States is 51.3 years but ranges from 45 to 55 years old.

Prevalence
- Approximately 40–54% of postmenopausal women are affected.
- Approximately 15% of premenopausal women are also affected.
- This condition is likely underdiagnosed because patients may be reluctant to report symptoms because of embarrassment or the misconception that symptoms should be accepted as a natural part of aging (1).

ETIOLOGY AND PATHOPHYSIOLOGY
- Estrogen is vasoactive, increasing blood flow to target tissues, lubrication, and elasticity.
- Decreased estrogen levels in the vagina and vulva result in decreased blood flow and decreased lubrication and elasticity of vaginal and vulvar tissues as well as thinning of these tissues.
- Decreased cellular maturation results in decreased glycogen stores, which affects the normal vaginal flora and consequently the pH.
- The resulting increased pH impairs the viability of the normal flora, permitting the proliferation of fecal and other flora, resulting in UTIs and vaginal infections (1)[C].
- Estrogen deficiency is caused by the following:
  - Menopause (surgical or natural)
  - Premature ovarian failure (chemotherapy, radiation, autoimmune, anorexia, genetic)
  - Postpartum estrogen deficiency in lactating women
  - Medications that alter hormonal concentration, such as gonadotropin-releasing hormone agonists, tamoxifen, danazol, medroxyprogesterone, and aromatase inhibitors
– Elevated prolactin from hypothalamic–pituitary disorders

**Genetics**
No known pattern

**RISK FACTORS**
- Estrogen-deficient states, including lactation
- Smoking
- Alcohol abuse
- Sexual abstinence or decreased frequency of coital activity
- Lack of exercise
- Absence of vaginal childbirth
- Chemotherapy
- Radiation therapy

**COMMONLY ASSOCIATED CONDITIONS**
- Urge and stress urinary incontinence
- Pelvic organ prolapse
- Frequent UTIs
- Bacterial or fungal vulvovaginitis
- Vaginal stenosis
- Loss of libido
- Dyspareunia

**DIAGNOSIS**

**HISTORY**
- All female patients should be asked about symptoms because many women are embarrassed to discuss these issues with their health care providers (1).
  - Vaginal dryness
  - Dyspareunia
  - Pruritus
  - Burning
  - Pressure
  - Tenderness
  - Malodorous discharge
  - Urinary symptoms: dysuria, hematuria, frequency, infections, stress, and urge urinary incontinence
- Ask about exposure to radiation therapy and medications.
- Ask about self-treatment and products used.
- Determine exposure to irritants (e.g., soaps, feminine sprays, lotions, lubricants, constant pad use).

**PHYSICAL EXAM**
Evidence for the diagnosis includes the following:
- Loss of pubic hair
- Decreased vulvar and vaginal fullness
- Fusion of labia minora
- Vulvar erythema or ecchymosis
- Decreased vulvar subcuticular fat and moisture
- Pale-appearing, shiny, smooth vaginal and urethral epithelium
- Vaginal shortening, intolerance to speculum exams
- Loss of vaginal rugation
- Pelvic organ prolapse
- Urethral atrophy
- Atrophy of Bartholin glands
- Cervical atrophy and stenosis of os

**DIFFERENTIAL DIAGNOSIS**
- Malignancy
- Sexual trauma
- Infection secondary to foreign bodies (e.g., piercings)
- Dermatologic conditions of vulva and vagina:
  - Dermatitis
  - Lichen sclerosis
  - Lichen planus
- Bacterial or fungal vulvovaginitis

**DIAGNOSTIC TESTS & INTERPRETATION**
Because vulvovaginitis is a clinical diagnosis, labs are not always necessary, but if a dermatologic or oncologic condition is suspected, biopsy is recommended (2)[C].

**Initial Tests (lab, imaging)**
Lab tests are generally unnecessary to make the diagnosis. However, the following labs and imaging may be obtained as corroborative of clinical impression:
- Follicle-stimulating hormone (FSH) and estrogen levels. FSH rises and estrogen drops with menopause.
- Evaluate for infections via wet preparation and vaginal pH (usually >5).
- Urinalysis if suspected concomitant UTI
- Cytology for maturation index: Higher proportion of parabasal cells and lower proportion of intermediate and superficial cells indicate decreased maturation index.
- Transvaginal ultrasound: Endometrial stripe <5 mm indicates loss of estrogen stimulation.

**Follow-Up Tests & Special Considerations**
Drugs that may alter lab results:
- Estrogen therapy will alter the maturation index but may improve symptoms.
- Digoxin has estrogen-like properties.
- Tamoxifen may produce menopausal-type symptoms but also may act on genital tissues as a weak estrogen agonist.
- Progestins, danazol, and gonadotropin-releasing hormone agonists may produce a reversible pseudomenopausal state.
GENERAL MEASURES
- Wear loose-fitting, undyed cotton underwear.
- Avoid prolonged pad use, especially scented pads.
- Avoid feminine deodorant sprays and douching.
- Symptomatic relief, if needed (e.g., cool baths or compresses)
- Increase coital activity.
- Smoking cessation

MEDICATION
- Nonhormonal vaginal moisturizers and lubricants are generally regarded as first-line therapy for mildly symptomatic estrogen-deficient vulvovaginitis (1)[C], although one recent study has shown that neither nonhormonal vaginal moisturizers nor lubricants and vaginal estrogen provided greater benefit than placebo gel or tablet (3)[A].
  - Estrogen therapy is preferred for moderate to severe symptoms: Local hormonal therapy (vaginal estrogen) is the first-line hormonal treatment and can reverse atrophic changes and alleviate symptoms (1)[C].
    o Vaginal cream: Insert via applicator 2 to 4 g daily for 1 to 2 weeks, then 1 to 2 g daily for 1 to 2 weeks and then 1 g 1 to 3 times a week.
    o Vaginal estradiol 10-μg tablet: Insert via preloaded applicator each night for 14 days and then twice weekly.
    o Estradiol-containing vaginal ring 2 mg: Insert into vagina and replace every 3 months.
  - Systemic hormonal therapy is typically reserved for patients wanting treatment for vasomotor symptoms associated with estrogen deficiency in addition to atrophic vulvovaginitis.
    - Transdermal preparations may be safer from a cardiovascular standpoint than oral preparations. Systemic estrogen therapy should be used in the lowest possible dose for the shortest duration of time (4)[B].
    - Long-term therapy may be necessary due to the chronic nature of estrogen-deficient vulvovaginitis (5)[A].
  - Contraindications:
    o Breast or estrogen-dependent cancers
    o Undiagnosed vaginal bleeding
    o Thromboembolic disorders
    o Endometrial hyperplasia or cancer
    o Hypertension
    o Hyperlipidemia
    o Liver disease
    o History of stroke
    o Coronary heart disease
    o Smoking in ages >35 years
    o Migraines with neurologic symptoms
    o Acute cholecystitis/cholangitis
    o Pregnancy
- Nonestrogen therapy: ospemifene (Osphena) 60-mg tablet daily; recommended for women with estrogen-deficient vulvovaginitis not responsive to nonpharmacologic therapies and who cannot or prefer not to use a vaginal estrogen (1)[C],(6)[B]
  - Contraindications:
Breast or estrogen-dependent carcinoma
- Undiagnosed vaginal bleeding
- Thromboembolic disorders
- Thrombophlebitis
- Hepatic impairment

- Precautions: Any abnormal vaginal bleeding must be evaluated. Monitor for DVT and stroke.

ISSUES FOR REFERRAL
- Refer to urogynecologist for evaluation if symptomatic due to pelvic organ prolapse and/or refractory stress and urge urinary incontinence.
- Recurrent UTIs should be further evaluated and may require a referral to urogynecology and/or urology.

ADDITIONAL THERAPIES
- Laser therapy with fractional CO₂ has demonstrated promise in initial studies; however, randomized controlled trials with long-term follow-up are still needed (1)[C].
- Lasofoxifene (Fablyn, Opora) and oxytocin vaginal gel (Vagitocin) are under development but not yet approved (1)[C].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Management of this condition occurs primarily in the outpatient setting.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Follow up as needed to determine response to treatment and for adjustment of treatment regimen.

Patient Monitoring
Instruct the patient that symptoms should improve within 30 to 60 days. If they do not, reevaluate and reexamine for other causes.

DIET
Increased consumption of cranberry juice or extract to prevent recurrent UTIs has been recommended but not well supported by evidence.

PATIENT EDUCATION
- American College of Obstetricians and Gynecologists (ACOG), 409 12th St., SW, Washington, DC 20024-2188; 800-762-ACOG: http://www.acog.org/
- Lactating postpartum women with high levels of prolactin are in a hypoestrogenic state. These women should be instructed to use lubrication for symptoms of dyspareunia and reassured that the symptoms will resolve when they are no longer breastfeeding.

PROGNOSIS
The prognosis is good. Most symptoms will be alleviated with vaginal estrogen replacement therapy.

COMPLICATIONS
- Recurrent UTIs may occur in women with vaginal atrophy.
Vaginal atrophy predisposes patients to vaginal infections.

REFERENCES

ADDITIONAL READING

CODES

**ICD10**

- N95.2 Postmenopausal atrophic vaginitis
- E28.39 Other primary ovarian failure

CLINICAL PEARLS

- Estrogen-deficient vullovaginitis affects virtually all postmenopausal women to some degree as well as some premenopausal women.
- This disorder is associated with genital, urologic, and sexual symptoms including vaginal itching, vaginal dryness, urinary incontinence, increased urinary frequency, recurrent UTIs, and dyspareunia.
- Estrogen-deficient vullovaginitis is a clinical diagnosis; lab tests are generally unnecessary.
- Vaginal moisturizers and lubricants are first-line therapy for mild symptoms, and vaginal estrogen preparations, rather than systemic preparations, are the preferred hormonal therapy for women with moderate to severe symptoms of estrogen-deficient vullovaginitis.
VULVOVAGINITIS, PREPUBESCENT
Simon B. Griesbach, MD  Sara Berry, DO

BASICS

DESCRIPTION
- Vulvitis is inflammation of the external genitals.
- Vaginitis, often associated with vaginal discharge, is inflammation involving the vaginal mucosa.
- In premenarchal girls, vulvitis is usually primary with secondary extension into the vagina.
- Vulvovaginitis can be classified as either nonspecific or specific
- Systems affected: reproductive, integumentary

EPIDEMIOLOGY

Incidence
Unknown

Prevalence
Most common gynecologic problem in prepubertal girls

ETIOLOGY AND PATHOPHYSIOLOGY
- In the prepubertal child, levels of estrogen are low, leading to thin, immature, and fragile vaginal epithelium.
- Anatomically underdeveloped labia minora, absence of pubic hair, minimal adiposity of the labia majora, and close proximity of the introitus to the anus make contamination more likely (1).
- The prepubertal child also has an alkaline vaginal pH, with an absence of lactobacilli (1).
- Infectious organisms causing vulvovaginitis are typically respiratory, enteric, or rarely sexually transmitted.
- Most cases of pediatric vulvovaginitis are typically respiratory, enteric, or rarely sexually transmitted.
- Most cases of pediatric vulvovaginitis are classified as nonspecific vulvovaginitis and do not have an infectious etiology.
- Nonspecific vulvovaginitis causes include:
  - Poor perineal hygiene (wiping back to front) (2)
  - Nonspecific chemical irritants (bubble baths, scented soaps, laundry detergents)
  - Tight-fitting clothing or underwear made of synthetic materials
- Specific vulvovaginitis causes include:
  - Bacterial: The most common bacteria are introduced from respiratory and GI tracts.
    - The most common respiratory pathogen is Streptococcus pyogenes (3). Vulvitis may occur in the absence of respiratory symptoms.
    - Escherichia coli is the most common fecal pathogen.
    - Shigella vaginitis is associated with mucopurulent bloody discharge and is not always accompanied by a history of diarrhea.

ALERT
Presence of Neisseria gonorrhea or Chlamydia trachomatis strongly suggests sexual transmission and should prompt consideration of sexual abuse
– Enterobius vermicularis (pinworms)
  o Very common in young children and certain populations
  o Should be considered in children with vaginal itching and irritation
  o Most common symptom is nocturnal perineal itching

- Recurrent/chronic vulvovaginitis:
  – Anatomic abnormalities could include double vagina with fistula, ectopic ureter, and urethral prolapse.
  – Systemic inflammatory diseases
  – Other conditions, such as lichen sclerosus, vitiligo, psoriasis, and atopic dermatitis are possible.

- Foreign body
  – Presents with foul-smelling, bloody, or brown discharge from the vagina
  – Should be considered in patients with recurrent vulvovaginitis after other causes are ruled out.

**RISK FACTORS**
- Inadequate hand washing or perineal cleansing after urination and defecation increases risk (2).
- Wearing of tight-fitting clothing increases risk
- Obesity also predisposes to nonspecific vulvovaginitis (4).

**GENERAL PREVENTION**
- Good perineal hygiene (including wiping from front to back)
- Urination with legs spread apart and labia separated
- Avoidance of tight-fitting clothing and nonabsorbent underwear
- Avoidance of irritants such as harsh/perfumed soaps and bubble baths

**COMMONLY ASSOCIATED CONDITIONS**
Urinary tract infections are common in children with vulvovaginitis (4).

**DIAGNOSIS**

**HISTORY**
- In taking the history from pediatric patient, it is important to develop good rapport with the patient and family as both the history and physical exam are sensitive to discuss.
- Symptoms may include:
  – Vaginal discharge
  – Vaginal or anal itching, burning or discomfort
  – Vulvar redness
  – Dysuria or perineal pain during urination
  – Prepubertal vaginal bleeding
  – Enuresis or encopresis
- Obtain careful history addressing any recent respiratory or enteric infections in the patient or close contacts.
- Ask questions to determine character of any vaginal discharge, if present.
- Determine exposure to irritants that may predispose to vulvovaginitis.
- Inquire about patient’s toileting habits
  – Wiping technique
– Position of legs while urinating

PHYSICAL EXAM

● Inform patients and family that exam may be embarrassing and uncomfortable but not painful.
● Explain physical exam thoroughly to the patient and her caregivers prior to beginning, giving opportunities to ask questions.
● If exam provokes significant anxiety, consider deferring exam or, for urgent/emergent concerns, performing exam under anesthesia.
● Examine pediatric patients in two positions for best visualization:
  – Supine in frog-leg position: provides view of external anatomy; Valsalva brings distal vagina into view
  – Prone in knee–chest position: taking deep breath separates vaginal walls and provides view of internal vagina and cervix; foreign body can be seen in this position
● Look for:
  – Excoriation, erythema, swelling of the introitus, discharge, foreign body, lichenification of external skin
  – Evaluate degree of estrogenized tissue
● Perform rectovaginal exam if vaginal bleeding, abdominal pain, or in cases concerning for tumor or foreign body

DIFFERENTIAL DIAGNOSIS

● Contact dermatitis
● Eczema
● Psoriasis
● Lichen sclerosus

DIAGNOSTIC TESTS & INTERPRETATION

Diagnosis is often clinical with testing as needed in patients with history or exam concerning for an infectious cause.

Initial Tests (lab, imaging)

● The definitive diagnosis of bacterial vulvovaginitis requires a culture of vulvar and vaginal secretions
  – Collect this specimen with a moistened small-diameter collection swab
● Perform polymerase chain reaction for sexually transmitted infection (STI) or herpes virus if suspected.
● Potassium hydroxide and saline smears of vaginal discharge, if present, can aid in diagnoses of fungal or certain bacterial causes. They have limited sensitivity and specificity.
● Urinalysis and urine culture can be considered to evaluate for concurrent urinary infection
● Tape test can be considered to evaluate for pinworm; some treat based on history and exam alone due to low sensitivity of testing.

Follow-Up Tests & Special Considerations

Exploration of the vagina for a foreign body may be necessary in cases of persistent, recurrent vulvitis.

● If an anatomic abnormality is suspected, imaging may be necessary to confirm.
  – Consider consultation with a pediatric or adult gynecologist to determine the most appropriate imaging study.
Diagnostic Procedures/Other
If blood or foul-smelling discharge is present, visualization is mandatory:
- Place the child in the knee–chest position for best results. Hold the buttocks apart and slightly upward.
- Visualization of the vagina may rarely require use of a nasal speculum or infant laryngoscope.
- If available, consider referral to a provider with specific training/experience in this specialized exam.

Test Interpretation
Culture often reveals organisms identical to those cultured in asymptomatic individuals (Staphylococcus epidermidis, enterococci, E. coli, Streptococcus viridans or Bacteroides spp.). Symptomatic patients should be treated.

TREATMENT
- The typical colony count and bacterial mix are unknown in prepubescent girls. Antibiotic use should be directed against the species with the highest colony count.
- General hygiene should always be recommended.
- When no cause is identified, treatment should focus on hygiene as well as minimizing soap exposure and tight-fitting clothes (3).

GENERAL MEASURES
- Appropriate health care: outpatient (except where systemic illness requires hospital care)
- Soak the vulva/perineum in a small amount of clear, warm water for 15 minutes twice daily.
- Advise the patient to avoid wearing underwear to bed or to wear loose-fitting boxer-shorts bottoms with loose pajamas.
- Reinforce the importance of perineal hygiene.

MEDICATION
First Line
- To break the itching–scratching–infection cycle, consider using low-dose topical hydrocortisone cream for a limited time.
- Estrogen deficiency with labial adhesion/agglutination: estrogen cream 0.625 mg to fused area nightly for 2 weeks
- Emollients or barrier creams may offer symptomatic relief.
- Antibiotic use should be restricted to cases of bacterial infection only (5)[A].
- Specific organisms on culture
  - Group A Streptococcus, Streptococcus pneumoniae: penicillin V, 250 mg PO BID–TID for 10 days
  - Haemophilus influenzae: amoxicillin, 20 to 40 mg/kg/day PO divided TID for 7 days
  - Staphylococcus aureus: cephalexin, 25 to 50 mg/kg/day PO divided QID for 7 to 10 days or dicloxacillin, 25 mg/kg/day divided QID for 7 to 10 days or amoxicillin-clavulanate, 20 to 40 mg/kg/day PO divided BID for 7 to 10 days
  - S. pyogenes: amoxicillin, 50 mg/kg/day PO divided into 3 doses/day for 10 days
  - Candida sp.: topical nystatin, miconazole, clotrimazole, or terconazole
  - Shigella: trimethoprim/sulfamethoxazole or ampicillin for 5 days
– Pinworms: mebendazole, 100 mg PO once, repeated in 2 weeks
– Chlamydia trachomatis: ≤45 kg: erythromycin base, 50 mg/kg/day QID for 14 days; ≥45 kg and <8 years old: azithromycin, 1 g PO single dose; ≥45 kg and ≥8 years old: azithromycin, 1 g PO single dose or doxycycline 100 mg BID for 7 days
– Neisseria gonorrhoeae: ≤45 kg: ceftriaxone, 25–50 mg/kg up to 125 mg IM or IV once plus medication for chlamydia in adolescents; >45 kg: ceftriaxone, 250 mg IM or IV once plus medication for chlamydia in adolescents
– Trichomonas: metronidazole, 15 mg/kg/day PO divided TID (max 250 mg TID) for 7 days

ISSUES FOR REFERRAL
- Suspected sexual abuse
- Suspected anatomic abnormality (except minor labial agglutination)
- Persistent, severe, or recurrent infections
- Inability to tolerate physical exam with serious cause suspected

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Monitor for fever, pruritus, and vaginal discharge.

DIET
- Healthy balanced diet, high in fiber to prevent constipation
- Adequate fluid intake

PATIENT EDUCATION

Hygiene
- Urinate with legs apart, sitting forward to decrease likelihood urine will collect in the vagina.
  - Consider facing “backward” on toilet seat to facilitate this.
- Wipe front to back after elimination and avoid reuse of toilet paper.
- Avoid bubble baths and other irritating products.
- Clean daily with mild soap and water and dry gently with soft towel or cool hair dryer.
- Defer hair shampooing to the end of bath time; consider washing hair while standing up.
- Apply unscented ointments or barrier creams for skin protection.

COMPLICATIONS
- If an STI is identified and not treated effectively, the patient is at risk for pelvic inflammatory disease (PID).
- Untreated vulvovaginitis can cause labial adhesions
- Vaginismus

REFERENCES

ADDITIONAL READING

CODES
- ICD10
  - N76.0 Acute vaginitis
  - N77.1 Vaginitis, vulvitis and vulvovaginitis in dis classd elswhr

CLINICAL PEARLS
- Vulvovaginitis is the most common gynecologic problem in prepubescent girls.
- The hypoestrogenic state and prepubescent anatomy may increase susceptibility to vulvar and vaginal infection.
- Treatment is typically supportive (avoid scratching, warm soaks) but may require antibiotics if a bacterial infection is suspected.
- Isolating an infection with known sexual transmission should prompt further investigation.
- Recurrent or persistent vulvitis, especially with foul-smelling discharge, should prompt a skilled exam of the vagina for a retained foreign body (most common toilet paper).
- Good perineal hygiene will limit this condition.
BASICS

- Warts (verrucae) are benign growths that are confined to the epidermis. All warts are caused by the human papillomavirus (HPV). Warts can appear on any area of the skin or mucous membranes. Common warts are predominantly seen in children and young adults.
- Clinically, warts are described as follows:
  - Common warts (verrucae vulgaris)
  - Plantar warts (verrucae plantaris)
  - Flat warts (verrucae plana)
  - Genital warts (condyloma acuminatum)
  - Epidermodysplasia verruciformis is a rare, lifelong hereditary disorder characterized by chronic infection with HPV.
- System(s) affected: skin/exocrine

DESCRIPTION

- Common warts are most often found at sites subject to frequent trauma, such as the hands and feet. Because warts often vary widely in shape, size, and appearance, the various descriptive names for them generally reflect their clinical appearance, location, or both.
- For example: Filiform (fingerlike) warts are threadlike, planar warts are flat, and plantar warts are located on the plantar surfaces (soles) of the feet.
- Genital warts, or condyloma acuminata, may be large and cauliflower-like, or they may consist of small papules.
- Warts on mucous membranes (mucosal papillomas), such as those in the mouth or vagina, tend to be white in color due to moisture retention.

EPIDEMIOLOGY

Incidence
- Predominant age: young adults and children
- No sex predominance: female = male

Prevalence
- ~7–10% of the U.S. population
- Common warts appear 2 times as frequently in whites compared with blacks or Asians.

ETIOLOGY AND PATHOPHYSIOLOGY

- HPV is a double-stranded, circular, supercoiled DNA virus.
- The virus infects epidermal keratinocytes, stimulating cell proliferation.
- Various strains of DNA HPV: To date, >150 different subtypes have been identified.
- Common warts: HPV types 2 and 4 (most common), followed by types 1, 3, 27, 29, and 57
- Palmoplantar warts: HPV type 1 (most common), followed by types 2, 3, 4, 27, 29, and 57
- Flat warts: HPV types 3, 10, and 28
- Butcher warts: HPV type 7
- The virus is passed primarily through skin-to-skin contact or from the recently shed virus kept
intact in a moist, warm environment.

**RISK FACTORS**
- HIV/AIDS and other immunosuppressive diseases (e.g., lymphomas)
- Immunosuppressive drugs that decrease cell-mediated immunity (e.g., prednisone, cyclosporine, and chemotherapeutic agents)
- Pregnancy
- Handling raw meat, fish, or other types of animal matter in one’s occupation (e.g., butchers)
- Previous wart infection

**GENERAL PREVENTION**
There is no known way to prevent warts.

**DIAGNOSIS**
- Most often made on clinical appearance
- Skin biopsy, if necessary

**PHYSICAL EXAM**
- Distribution of warts is generally asymmetric, and lesions are often clustered or may appear in a linear configuration due to scratching (autoinoculation).
- Common wart: rough-surfaced, hyperkeratotic, papillomatous, raised, skin-colored to tan papules, 5 to 10 mm in diameter; several may coalesce into a larger cluster (mosaic wart); most frequently seen on hands, knees, and elbows; usually asymptomatic but may cause cosmetic disfigurement or tenderness
- Filiform warts: These are long, slender, delicate, fingerlike growths, usually seen on the face around the lips, eyelids, or nares.
- Plantar warts often have a rough surface and appear on the plantar surface of the feet in children and young adults.
  - Can be tender and painful; extensive involvement on the sole of the foot may impair ambulation, particularly when present on a weight-bearing surface.
  - Most often seen on the metatarsal area, heels, and toes in an asymmetric distribution (pressure points)
  - Pathognomonic “black dots” (thrombosed dermal capillaries); punctate bleeding becomes more evident after paring with a no. 15 blade.
  - Both common and plantar warts generally demonstrate the following clinical findings:
    - A loss of normal skin markings (dermatoglyphics) such as finger, foot, and hand prints
    - Lesions may be solitary or multiple, or they may appear in clusters (mosaic warts).
- Flat warts: slightly elevated, flat-topped, skin-colored or tan papules, small (1 to 3 mm) in diameter
  - Commonly found on the face, arms, dorsa of hands, shins (women)
  - Sometimes exhibit a linear configuration caused by autoinoculation
  - In men, shaving spreads flat warts.
  - In women, they often occur on the shins where leg shaving spreads lesions.
- Epidermodysplasia verruciformis (rare): Widespread flat, reddish brown pigmented papules and plaques that present in childhood with lifelong persistence on the trunk, hands, upper and lower extremities, and face are characteristics.
DIFFERENTIAL DIAGNOSIS

- Molluscum contagiosum
- Seborrheic keratosis
- Epidermal nevus
- Acrochordon (skin tag)
- Solar keratosis and cutaneous horn
- Acquired digital fibrokeratoma
- Squamous cell carcinoma (SCC)
- Keratoacanthoma
- Subungual SCC can easily be misdiagnosed as a subungual wart or onychomycosis.
- Corns/calluses
  - Corns (clavi) are sometimes difficult to distinguish from plantar warts. Like calluses, corns are thickened areas of the skin and most commonly develop at sites subjected to repeated friction and pressure, such as the tops and the tips of toes and along the sides of the feet.
  - Corns are usually hard and circular, with a polished or central translucent core, like the kernel of corn from which they take their name.
  - Corns do not have “black dots,” and skin markings are retained, except for the area of the central core.

ALERT

- A melanoma on the plantar surface of the foot can mimic a plantar wart.
- Verrucous carcinoma, a slow-growing, locally invasive, well-differentiated SCC, also may be easily mistaken for a common or plantar wart.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

Diagnosis

- HPV cannot be cultured, and lab testing is rarely necessary.
- Definitive HPV diagnosis can be achieved by the following:
  - Electron microscopy
  - Viral DNA identification employing Southern blot hybridization is used to identify the specific HPV type present in tissue.
  - Polymerase chain reaction may be used to amplify viral DNA for testing.

Follow-Up Tests & Special Considerations

Skin biopsy if unusual presentation or if diagnosis is unclear

Test Interpretation

- Histopathologic features of common warts include digitated epidermal hyperplasia, acanthosis, papillomatosis, compact orthokeratosis, hypergranulosis, dilated tortuous capillaries within the dermal papillae, and vertical tiers of parakeratotic cells with entrapped red blood cells above the tips of the digitations.
- In the granular layer, HPV-infected cells may have coarse keratohyalin granules and vacuoles surrounding wrinkled-appearing nuclei. These koilocytic (vacuolated) cells are pathognomonic for warts.
TREATMENT

The abundance of therapeutic modalities described below is a reflection of the fact that none of them is uniformly or even clearly effective in trials. Placebo treatment response rate is significant, and quality of evidence in general is poor. Beyond topical salicylates, there is no clear evidence-based rationale for choosing one method over another (1)[A].

The choice of method of treatment depends on the following:

- Age of the patient
- Cosmetic and psychological considerations
- Relief of symptoms
- Patient’s pain threshold
- Type of wart
- Location of the wart
- Experience of the physician

GENERAL MEASURES

- There is no ideal treatment.
- In children, most warts tend to regress spontaneously.
- In many adults and immunocompromised patients, warts are often difficult to eradicate.
- Painful, aggressive therapy should be avoided unless there is a need to eliminate the wart(s).
- For surgical procedures, especially in anxious children, pretreat with anesthetic cream such as EMLA (emulsion of lidocaine and prilocaine).

MEDICATION

First Line

- Self-administered topical therapy
  - Keratolytic (peeling) agents: The affected area(s) should be hydrated first by soaking in warm water for 5 minutes before application. Most over-the-counter agents contain salicylic acid and/or lactic acid: agents such as Duofilm, Occlusal-HP, Trans-Ver-Sal, and Mediplast.
- Office based
  - Cantharidin 0.7%, an extract of the blister beetle that causes epidermal necrosis and blistering but may be difficult to obtain as a solution in the United States. It may be compounded in compounding pharmacies.
  - Combination cantharidin 1%, salicylic acid 30%, and podophyllin resin 5% in flexible collodion; applied in a thin coat, occluded 4 to 6 hours and then washed off

Second Line

- Home based
  - Imiquimod 5% (Aldara) cream, a local inducer of interferon, is applied at home by the patient. It is approved for external genital and perianal warts and is used off-label and may be applied to warts under duct tape occlusion. It is applied at bedtime and washed off after 6 to 10 hours; applied to flat warts without occlusion
  - Topical retinoids (e.g., tretinoin 0.025–0.1% cream or gel) for flat warts
- Office based
  - Immunotherapy: induction of delayed-type hypersensitivity with the following:
    - Diphenylcyclopropenone (DCP) (2)[B]
    - Dinitrochlorobenzene (DNCB)
Squaric acid dibutylester (SADBE): There is possible mutagenicity and side effects with this agent.

- Intralesional injections
  - Mumps or Candida antigen
  - Bleomycin: Intradermal injection is expensive and usually causes severe pain.
  - Interferon-α-2b

- Oral therapy
  - Oral high-dose cimetidine: possibly works better in children (40 mg/kg/day; max 1,600 mg)
  - Acitretin (an oral retinoid)

- Other treatments (all have all been used with varying results)
  - Dichloroacetic acid, trichloroacetic acid, podophyllin, formic acid, aminolevulinic acid in combination with blue light, 5-fluorouracil, silver nitrate, formaldehyde, levamisole, topical cidofovir (3)[B] or IV cidofovir for recalcitrant warts in the setting of HIV, and glutaraldehyde
  - The quadrivalent HPV vaccine has cleared recalcitrant, chronic oral, and cutaneous warts (4)[C].

SURGERY/OTHER PROCEDURES

- Cryotherapy with liquid nitrogen (LN₂) may be applied with a cotton swab or with a cryotherapy gun (Cryogun). Aggressive cryotherapy may be more effective than salicylic acid (5)[A], but it is associated with increased adverse effects (blistering and scarring):
  - Best for warts on hands; also during pregnancy and breastfeeding
  - Fast; can treat many lesions per visit
  - Painful; not tolerated well by young children
  - Freezing periungual warts may result in nail deformation.
  - In darkly pigmented skin, treatment can result in hypo- or hyperpigmentation.
  - Uneven uptake of LN2 can result in a larger ring wart.

- Light electroyautery with or without curettage
  - Best for warts on the knees, elbows, and dorsa of hands
  - Also good for filiform warts
  - Tolerable in most adults
  - Requires local anesthesia
  - May cause scarring

- Photodynamic therapy: Topical 5-aminolevulinic acid is applied to warts followed by photoactivation.

- CO₂ or pulse-dye laser ablation: expensive and requires local anesthesia

- For filiform warts: Dip hemostat into LN₂ for 10 seconds, then gently grasp the wart for 10 seconds and repeat. Wart sheds in 7 to 10 days.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Duct tape: Cover wart with waterproof tape (e.g., duct tape). Leave the tape on for 6 days and then soak, pare with emery board, and leave uncovered overnight; then reapply tape cyclically for eight cycles; 85% resolved compared with 60% efficacy with cryotherapy (6)[A]

- Hyperthermia: safe and inexpensive approach; immerse affected area into 45°C water bath for 30 minutes 3 times per week.

- Hypnotherapy
Raw garlic cloves have demonstrated some antiviral activity.

Vaccines are currently in development.

**Pregnancy Considerations**
The use of some topical chemical approaches may be contraindicated during pregnancy or in women who are likely to become pregnant during the treatment period.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
1/3 of the warts of epidermodysplasia may become malignant.

**PROGNOSIS**
- More often than not (especially in children), warts tend to “cure” themselves over time.
- In many adults and immunocompromised patients, warts often prove difficult to eradicate.
- Rarely, certain types of lesions may transform into carcinomas.

**COMPLICATIONS**
- Autoinoculation (pseudo-Koebner reaction)
- Scar formation
- Chronic pain after plantar wart removal or scar formation
- Nail deformity after injury to nail matrix

**REFERENCES**

**ADDITIONAL READING**

CODES

ICD10

- B07.9 Viral wart, unspecified
- B07.0 Plantar wart
- A63.0 Anogenital (venereal) warts

CLINICAL PEARLS

- No single therapy for warts is uniformly effective or superior; thus, treatment involves a certain amount of trial and error.
- Because most warts in children tend to regress spontaneously within 2 years, benign neglect is often a prudent option.
- Conservative, nonscarring, least painful, least expensive treatments are preferred.
- Freezing and other destructive treatment modalities do not kill the virus but merely destroy the cells that harbor HPV, triggering host immune repair response.
WILMS TUMOR
Chad Hamner, MD

BASICS

DESCRIPTION
- Most common renal tumor in children; fifth most common pediatric malignancy
- An embryonal renal neoplasm containing blastemal, stromal, or epithelial cell types, usually affecting children <5 years of age.
- Staging: In the United States, Children’s Oncology Group (COG) Renal Tumor Committee (formerly National Wilms Tumor Study [NWTS] group) staging is done pretreatment. In Europe/Asia, staging is done after neoadjuvant chemotherapy (1).
- COG Renal Tumor Committee Stage (incidence) (1):
  - I: completely excised tumor limited to kidney; negative lymph nodes (43%)
  - II: completely excised tumor extends beyond kidney capsule or renal sinus vessels contain tumor; atriocaval thrombus if removed en bloc with tumor; negative lymph nodes (20%)
  - III: residual nonhematogenous tumor confined to abdomen (spillage of tumor or previous biopsy, peritoneal implants, extension beyond resection region, atriocaval thrombus above diaphragm not removed en bloc with kidney) or positive lymph nodes (21%)
  - IV: hematogenous metastases (lung most common, liver, brain, or bones) or lymph node involvement outside the abdomen or pelvis (11%)
  - V: bilateral renal involvement (5%)
- System(s) affected: renal/urologic
- Synonym(s): nephroblastoma

Pediatric Considerations
Occurs predominately in children; rare incidence in late adolescence and adults

EPIDEMIOLOGY

Incidence
- Represents 6–7% of all childhood cancers
- Wilms tumor comprises 95% of all renal cancers in children <15 years.
- 650 cases diagnosed annually, with incidence of 7.8 cases per 1 million children
- Bilateral renal involvement approximately 5%.
- Frequency higher in black children.
- Predominant age: median age of 36.5 months:
  - >80% diagnosed before 5 years of age.
  - Diagnosis for bilateral Wilms tumor (mean 31 months) than unilateral tumor (mean 44 months).
- Predominant sex: female > male (1.1:1)
  - Higher rate of bilateral Wilms tumor in females (1.7:1) (1)

Prevalence
- United States: 0.69 per 100,000 children
- Globally: 1 per 10,000 children
ETIOLOGY AND PATHOPHYSIOLOGY
- Thought to be more than one genetic alteration affecting embryologic renal development or epigenetic regulation.
- Majority occur sporadically; familial inheritance <2% (1)

Genetics
- Tumors display recurrent gene mutations involved in either early renal development or epigenetic regulation (e.g., chromatin modification, transcription regulation, miRNA).
- 1/3 of tumors involve mutations of WT1, CTNNB1, or WTX genes (1).

RISK FACTORS
- Increased predisposition associated with syndromes (e.g., Beckwith-Wiedemann, WAGR, Denys-Drash)
- Race: more frequent in black children; rare in Asian
- Sex: more frequent and higher rate of bilateral in females

GENERAL PREVENTION
- 2016 American Association for Cancer Research (AACR) Childhood Cancer Predisposition Workshop recommends uniform screening for all syndromes associated with >1% risk of Wilms tumor (1):
  - Routine screening with serial renal ultrasound (US) at 3-month intervals, usually until age 8
- Genetic counseling recommended for children with Wilms tumor and (1):
  - One major abnormality: overgrowth syndromes, hemihyperplasia, aniridia, mental retardation, diffuse mesangial sclerosis; or
  - Two minor malformations - inguinal or umbilical hernia, hypospadias, renal abnormalities, ectopic testis

COMMONLY ASSOCIATED CONDITIONS
- Associated conditions grouped into overgrowth and non-overgrowth categories
- Overgrowth syndromes and conditions (1)
  - Beckwith-Wiedemann syndrome
  - Isolated hemihyperplasia
  - Pearlman syndrome
  - Simpson-Golabi-Behmal syndrome
  - CLOVES syndrome
  - Sotos syndrome
- Non-overgrowth syndromes and conditions (1)
  - Denys Drash and Frasier
  - WAGR syndrome
  - Sporadic
  - Familial Wilms tumor
  - Bohring-Opitz syndrome
  - Bloom syndrome
  - Li-Fraumeni syndrome
  - Fanconi anemia
  - Alagille syndrome
  - Trisomy 18
  - Genitourinary
DIAGNOSIS

HISTORY
- >90% present with asymptomatic abdominal mass
- Most common symptoms and signs: abdomen pain (40%), hypertension (25%), gross hematuria (18%)
- Associated symptoms (10%): fever, weight loss, anorexia, malaise
- History of increasing abdominal size

PHYSICAL EXAM
- Palpable upper abdominal mass
- Hypertension
- Fever
- Hepatosplenomegaly
- Ascites
- Prominent abdominal wall veins
- Varicocele
- Cardiac murmur

DIFFERENTIAL DIAGNOSIS
- Neuroblastoma
- Hepatic tumor
- Sarcoma
- Rhabdoid tumor
- Cystic nephroma
- Clear cell renal sarcoma
- Renal cell carcinoma
- Mesoblastic nephroma
- Nephroblastomatosis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Urinalysis (occasional hematuria, proteinuria)
- CBC (anemia)
- Renal function studies
- Liver function studies
- Coagulation factors (association with acquired von Willebrand factor deficiency)
- Lactate dehydrogenase
- Urine catecholamines (present with neuroblastoma)
- Chest radiograph
- Abdominal US (with Doppler imaging): best initial test; also provides information about tumor thrombus extension into inferior vena cava (found in 6–10% of tumors)
- CT scan (with IV and oral contrast material) of chest and abdomen:
  - Provide anatomic visualization for surgical planning.
- MRI of abdomen and chest may be used as alternative to CT; routine use limited by need for sedation in young children.
Diagnostic Procedures/Other

- Tumor biopsy should be avoided as violation of the tumor capsule upstages the local disease (stage III), requiring additional chemotherapy and abdominal radiation therapy.
- In the United States, attempted surgical resection with aortocaval lymph node sampling is recommended for unilateral tumors to provide local disease clearance and tumor biology needed for therapeutic risk group stratification.
- Contraindications to upfront resection:
  - The presence of lung metastases does not typically influence indication for tumor resection [2].

Test Interpretation

- COG protocols group histologic features into favorable and unfavorable categories [1]:
  - Favorable histology, present in 90% of tumors (survival rate >90%):
    - Triphasic pattern of blastemal, stromal, and epithelial elements
    - Predominance of blastemal elements indicates more aggressive tumors.
  - Unfavorable histology (anaplasia), present in 10% of tumors (survival rate 33–85%)
    - Anaplasia defined as hyperchromatic, markedly enlarged pleomorphic nuclei (3 times larger than adjacent cells) with multipolar polyloid mitotic figures.
    - Focal or diffuse pattern
    - Single most important histologic predictor of survival and response to treatment; diffuse pattern associated with worse prognosis than focal pattern.
- Nephrogenic rests identified in 35% on unilateral tumors and up to 100% of bilateral tumors [1]

TREATMENT

GENERAL MEASURES

- All patients with Wilms tumor should be considered for entry into available clinical trials.
- Treatment combines surgical resection, postoperative with or without neoadjuvant combination chemotherapy, and radiation therapy reserved for advanced stage disease.
- Risk stratification is used to determine appropriate treatment for both COG and SIOP protocols [2]:
  - Neoadjuvant chemotherapy following biopsy (percutaneous or open) indicated in COG protocols for following situations [1,2][B]:
    - Tumor in solitary kidney or synchronous bilateral tumors: high risk for renal failure; tumor shrinkage may allow partial nephrectomy.
    - Extensive caval thrombus above the hepatic veins: increased intraoperative bleeding risk; thrombus often regresses with chemotherapy.
    - Locally invasive tumor requiring removal of contiguous organs for resection (e.g., spleen, pancreas, colon, not including adrenal gland)
    - Inoperable tumors
    - Pulmonary compromise due to extensive metastases
  - Radiation therapy reserved for advanced stage disease (stage III and IV) and anaplastic tumors: [1,2][B]
– Abdomen radiation included for incompletely resected tumor, tumor spillage, or anaplastic tumor despite complete resection.
– Whole lung radiation reserved for imaging confirmed lung metastases; may be omitted in patients with complete radiologic response to chemotherapy
– Directed radiation to other sites of metastases (e.g., bone) may also be included.

Nephrectomy alone may be offered to select children (<2 years) with small (<550 gm), stage I, favorable histology tumors (1,2)[B]

MEDICATION

First Line
Four chemotherapy regimens are used as standard therapy (1):
- EE-4A: Vincristine and Dactinomycin; 18 weeks duration after nephrectomy
- DD-4A: Vincristine, Dactinomycin, and Doxorubicin; 24 weeks duration after nephrectomy or biopsy with subsequent nephrectomy
- I: Vincristine, Doxorubicin, Cyclophosphamide, and Etoposide; 24 weeks after nephrectomy
- M: Vincristine, Dactinomycin, Doxorubicin (DD-4A) plus Cyclophosphamide and Etoposide; time frame variable

Second Line
- Carboplatin
- Irinotecan
- Ifosfamide

ISSUES FOR REFERRAL
All patients with Wilms tumor should be considered for entry into available clinical trials and referred to a multidisciplinary team specializing in pediatric cancer.

ADDITIONAL THERAPIES
High dose chemotherapy plus autologous hemopoietic stem cell rescue has been utilized for relapsed disease.

SURGERY/OTHER PROCEDURES
- Unilateral Wilms tumor: radical nephroureterectomy through transabdominal or thoracoabdominal incision with renal hilar and aortocaval lymph node sampling.
  – Exploration of contralateral kidney not required if preoperative CT adequately delineates unilateral disease.
  – Palpation of the renal vein and inferior vena cava should be performed to assess for tumor thrombus
  – Presence of lung metastases does not preclude local tumor resection.
  – Resection of contiguous organs should be avoided
  – Hepatic metastectomy is not recommended.
  – Nephron-sparing surgery (partial nephrectomy) remains controversial.
- Bilateral Wilms tumors: goal of surgery is to eradicate all tumor while preserving functional renal tissue (1)
  – Preoperative chemotherapy recommended with re-evaluation by CT or MRI after 6 weeks
  – Nephron-sparing operation undertaken at 6 weeks if good response to chemotherapy:
    o Partial nephrectomy or wedge excision of tumor is preferred.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Multidrug chemotherapy every 3 to 4 weeks for 16 weeks to 15 months depending on stage, then every 4 months for 1 year, every 6 months for 2nd to 3rd year, and yearly after that.
- CBC, CT of chest and abdomen with each visit

PATIENT EDUCATION
Possibility of second malignancy (up to 4% by age 30 years, median 12.5 years to onset)

PROGNOSIS
- Outcomes are reported as 4-year event-free survival (EFS) and 4-year overall survival (OS)
- Favorable histology tumors (1)
  - Stage I (NWTS-5 study, COG protocol ARENO 532):
    - Children <2 years of age, tumor weight <550 gm (surgery only): 90% EFS, 100% OS
    - Children ≥2 years of age or tumor weight ≥550 gm (surgery + regimen EE-4A): 94% EFS, 98% OS
  - Stage II (surgery + regimen EE-4A): 86% EFS, 98% OS
  - Stage III (surgery + regimen DD-4A + abdominal radiation therapy [XRT]):
    - All patients: EFS 88%, OS 97%
  - Stage IV and lung metastases response to therapy:
    - Complete response (surgery + regimen DD-4A + abdominal and whole lung XRT): 80% EVS, 96% OS
    - Incomplete response (surgery + regimen M + abdominal and whole lung XRT): 85% EVS, 95% OS
- Unfavorable histology tumors with focal anaplasia (NWTS-5 study) (1)
  - Stage I (surgery + regimen EE-4A + abdomen XRT): 68% EFS, 89% OS
  - Stage II (surgery + regimen DD-4A + abdomen XRT): 80% EFS, 80% OS
  - Stage III (surgery + post-nephrectomy or neoadjuvant regimen DD-4A + abdomen XRT)
    - Post-nephrectomy chemotherapy group: 88% EFS, 100% OS
  - Stage IV (surgery + regimen DD-4A + abdomen and whole lung XRT): 61% EFS, 72% OS
- Unfavorable histology tumors with diffuse anaplasia (NWTS-5 study) (1)
  - Stage I (surgery + regimen EE-4A + abdomen XRT): 68% EFS, 79% OS
  - Stage II (surgery + regimen DD-4A + abdomen XRT): 83% EFS, 82% OS
  - Stage III (surgery + post-nephrectomy or neoadjuvant regimen I + abdomen XRT)
  - Stage IV (surgery + post-nephrectomy or neoadjuvant regimen I + abdomen and whole lung XRT)
    - Post-nephrectomy chemotherapy group: 33% EFS, 33% OS
- Bilateral tumors (stage V) (1,2)
  - COG protocol ARENO 0544 (induction DD-4A + bilateral surgery 12 weeks from diagnosis + histology based postoperative chemotherapy +/- XRT)
    - All histologies EFS 82.1%, OS 94.9%; favorable histology 84% EFS; anaplasia 58% EFS
- Survival with relapsed Wilms tumor is 40–60%.

COMPLICATIONS
Surgical complications include intestinal obstruction (5%), extensive hemorrhage (2%), wound infection (2%), and vascular injury (1.5%).
Cumulative incidence of severe chronic health condition 25 years after surgery is 65%.
Premature mortality: 5–23% cumulative mortality 30–50 years after diagnosis (1):
- Excess deaths related to secondary malignancy (50%) and congestive heart failure (25%).
- Radiation therapy is a major risk factor.
Recurrent Wilms tumor typically occurs in the lungs within 2 years of diagnosis.

REFERENCES

CODES
ICD10
- C64.9 Malignant neoplasm of unsp kidney, except renal pelvis
- C64.1 Malignant neoplasm of right kidney, except renal pelvis
- C64.2 Malignant neoplasm of left kidney, except renal pelvis

CLINICAL PEARLS
- Wilms is the most common renal tumor in children; usually affecting children <5 years of age.
- Overall survival ranges from 30–100% with worse outcomes associated with anaplasia, advanced stage, and loss of heterozygosity of chromosome 1p and 16q.
ZOLLINGER-ELLISON SYNDROME
Douglas S. Parks, MD

BASICS

DESCRIPTION
- Zollinger-Ellison syndrome (ZES) triad
  - Markedly elevated gastric acid secretion
  - Peptic ulcer disease
  - A gastrinoma or non-β islet cell tumor of the pancreas or duodenal wall that produces gastrin (hypergastrinemia)
    - Gastrinomas (at the time of diagnosis) may be single or multiple (1/2 to 2/3), large or small, benign or malignant (2/3), sporadic (70–75%) or associated with multiple endocrine neoplasia type 1 (MEN1) (25–30%).
- System(s) affected: endocrine/metabolic, gastrointestinal
- Synonym(s): Z-E syndrome; pancreatic ulcerogenic tumor syndrome; multiple endocrine neoplasia, partial; ulcerogenic islet cell tumor

EPIDEMIOLOGY

Incidence
- 1 to 3 per million per year in the United States
- Predominant age: middle age (30 to 65 years). Mean age of onset is 43 years; presents a decade earlier in patients with ZES/MEN1
- Predominant sex: male > female (1.3:1)

Pediatric Considerations
Aggressive cases have been reported in teenagers.

Pregnancy Considerations
Rare; pregnancy alters medication choices and surgical timing.

ETIOLOGY AND PATHOPHYSIOLOGY

- Gastrinoma is found in the head of the pancreas (20–30%) and the first or second portion of the duodenum (70–80%); if in the pancreas, the lesion is more likely to metastasize to the liver (1).
- Hypergastrinemia results in gastric mucosal hypertrophy and increased acid production. Increased acid production causes mucosal ulceration. Diarrhea (60%) and malabsorption are also common in ZES (1).
- Increasing number found in stomach wall, up to 8%; may be due to increased surveillance and/or increased proton pump inhibitor (PPI) use masking symptoms
- Also may be found rarely in the mesentery, peritoneum, spleen, skin, or mediastinum (possibly metastasis with primary not identified)

Genetics
- ~25–30% of cases occur in association with the autosomal dominant MEN1 syndrome—tumors of pancreas, pituitary, and parathyroid.
Can occur sporadically as well

**RISK FACTORS**
- MEN1
- Family history of ulcer disease

**GENERAL PREVENTION**
Screen first-degree relatives of patients with MEN1.

**COMMONLY ASSOCIATED CONDITIONS**
- MEN1
- Insulinoma
- Carcinoid tumors

**DIAGNOSIS**

**HISTORY**
Average of 5 years of symptoms (including recurrent ulcers) before diagnosis is made
- Abdominal pain is the most common symptom (80%).
- Diarrhea (postprandial and fasting) (70%)
- Heartburn (60%)
- Nausea (30%)
- Reflux esophagitis
- Vomiting that is unresponsive to standard therapy
- Weight loss

**PHYSICAL EXAM**
- Hepatomegaly with metastasis
- Conjunctival pallor if anemic
- Jaundice (tumor compressing common bile duct)
- Epigastric tenderness
- Dental erosions
- Heme + stools on rectal exam
- Complications of severe peptic ulcer disease, including hemorrhage, perforation, and obstruction
- Signs of MEN1 are hypercalcemia, hyperparathyroidism, and Cushing syndrome.

**Geriatric Considerations**
Consider the diagnosis in a patient with persistent or recurring peptic ulcer disease; it is a less aggressive disease if it appears after 65 years.

**DIFFERENTIAL DIAGNOSIS**
- Elevated serum gastrin with hypochlorhydria/achlorhydria
  - Atrophic gastritis
  - Drug-induced (associated with PPIs)
  - Gastric cancer
  - Pernicious anemia
  - Postvagotomy
Elevated serum gastrin with normal or increased gastric acid
  – Antral G-cell hyperfunction
  – Chronic renal failure
  – Helicobacter pylori infection
  – Gastric outlet obstruction
  – Retained gastric antrum
• Consider gastrinoma in all patients with:
  – Recurrent or refractory ulcer disease
  – Gastric hypertrophy and ulcers
  – Duodenal and jejunal ulcers
  – Ulcers and diarrhea
  – Ulcers and kidney stones
  – Hypercalcemia and ulcers
  – Pituitary disease
  – Family history of ulcer disease or endocrine tumors suggestive of MEN1

DIAGNOSTIC TESTS & INTERPRETATION
• Secretin stimulation test is preferred: gastrin level >120 pg/mL (>120 ng/L); may be difficult to find lab that can do this (1,2)
• Some gastrin assays undermeasure serum gastrin; if have strong index of suspicion but gastrin levels low, may need to repeat with a different lab (1)
• Gastric secretory studies: basal acid output
• Elevated fasting serum gastrin: >1,000 pg/mL with ulcers diagnostic; >200 pg/mL with ulcers is suggestive.
• Elevated basal gastric acid output: >15 mEq/hr (>15 mmol/hr)
• Gastric pH <2 with elevated gastrin
• Check serum calcium, phosphorus, cortisol, and prolactin to rule out MEN1.
• Drugs may alter lab results:
  – Histamine (H₂) blockers and PPIs may increase gastric pH and serum gastrin.
  – Hold PPIs 7 days and H₂ blockers 2 days prior to drawing gastrin level.
• Endoscopic ultrasound (US): finds 24–38% of primary tumors in pancreas, much less effective in duodenum
• Endoscopic findings include esophagitis, duodenal ulceration with multiple ulcers, and prominent gastric and duodenal folds.
• Used to localize tumor for possible resection
• Much more likely to find tumors >3 cm (95%) than <1 cm (<15%)
• Abdominal CT scan: most useful for pancreatic tumors and metastasis >3 cm
• Abdominal US, MRI, and angiography are not typically useful except in large tumors.
• Somatostatin receptor scintigraphy (SRS): more sensitive than radiologic studies, still only finds 30% of small tumors
• Newest modality is ⁶⁸Gallium labeled somatostating PET/CT scanning which is showing excellent sensitivity and specificity (1,2)
• Portal venous sampling and selective venous sampling for gastrin can localize the area of tumor and metastasis (80–90% sensitivity) for surgical intervention (3).
• Brain imaging (MRI) and serum calcium are useful if MEN1 is suspected.
• Because pancreatic tumors are most likely to be large and to metastasize to the liver (worse
prognosis), SRS and an abdominal CT scan are suggested to look for resectable tumors. Resection improves prognosis.

**Initial Tests (lab, imaging)**
- Diagnosis is based on elevated fasting plasma gastrin levels and gastric pH <2 in the absence of PPI or H₂ blockers.
- Radiologic studies help locate and identify tumors for resection (1,2,3).

**Follow-Up Tests & Special Considerations**
Annual radiologic studies to look for recurrent or growing tumors and liver metastasis that may require reoperation (4)

**Diagnostic Procedures/Other**
Endoscopy may reveal tumors in the duodenal or stomach wall; multiple ulcers, including jejunal ulcers; and prominent gastric and duodenal folds.

**Test Interpretation**
- 90% of gastrinomas are found in the gastric triangle (bordered by the bile duct, the junction of second and third portions of the duodenum, and the junction of the head and body of pancreas).
- ~30% of gastrinomas are in the head of the pancreas (more likely >3 cm, metastasis to liver).
- ~70% of gastrinomas are in the wall of the first or second portion of duodenum (more likely small and solitary) (2).
- 2/3 of gastrinomas are malignant.
- 50% of gastrinomas stain positive for adrenocorticotropic hormone (ACTH), vasoactive intestinal polypeptide, insulin, or neurotensin.
- 1/3 of patients have metastasis on presentation: regional nodes > liver, > bone, > peritoneum, spleen, skin, and mediastinum.
- Biopsy shows hyperplasia of antral gastrin-producing cells; histology appears similar to carcinoid.

**TREATMENT**

**GENERAL MEASURES**
- Goals are to control acid hypersecretion and resect the tumor.
- Advanced imaging initially to evaluate for resection
- Surgical removal when primary tumor can be identified and as adjunct to control symptoms.
  Surgical resection of primary may enable stopping acid secretion and need for medical treatment (3).
- Medical treatment for symptom control when primary tumor is not found or metastasis on initial diagnosis

**MEDICATION**
- PPIs are the first-line treatment; add H₂ blockers if PPI not tolerated or insufficient.
- Medications heal 80–85% of ulcers, most of which recur. Lifelong medication use should be anticipated.
- 4- to 8-fold higher H₂ dose often necessary; may need up to double dose of PPI (3)
- Start at a lower dose, and titrate to symptoms (or maximum recommended dosage).
- If hyperparathyroidism is present (MEN1), correct hypercalcemia.

**First Line**

- **PPIs**
  - Omeprazole 60 to 120 mg/day
  - Lansoprazole 60 to 180 mg/day (doses >120 mg need to be divided BID)
  - Rabeprazole 60 to 100 mg/day; up to 60 mg BID
  - Pantoprazole 40 to 240 mg/day PO; 80 to 120 mg q12h IV

- **H₂ blockers**
  - Cimetidine 300 mg q6h; up to 2.4 g/day
  - Ranitidine 150 mg q12h; up to 6 g/day
  - Famotidine 20 mg q6h; up to 640 mg/day

- **Contraindications**
  - Known hypersensitivity to the drug
  - H₂ blockers: antiandrogen effects, drug interactions due to cytochrome P450 inhibition
  - PPIs: none

- **Precautions**
  - Adjust doses for geriatric patients and patients with renal insufficiency.
  - Gynecomastia has been reported with high-dose cimetidine (>2.4 g/day).
  - PPIs may induce a profound and long-lasting effect on gastric acid secretion, thereby affecting the bioavailability of drugs depending on low gastric pH (e.g., ketoconazole, ampicillin, iron).

  Significant possible interactions: Consider drug–drug interactions and consult prescribing materials accordingly.

**Second Line**

- Octreotide may slow growth of liver metastases or (occasionally) promote regression.
  - Octreotide LAR can be given every 28 days.
- Chemotherapy regimens using streptozocin, 5-fluorouracil, and doxorubicin shows limited response.
- Interferon shows a limited response but may be useful in combination with octreotide.

**SURGERY/OTHER PROCEDURES**

- Laparotomy to search for resectable tumors unless patient has liver metastasis on presentation or MEN1; surgery improves outcomes.
- Definitive therapy: removal of identifiable gastrinomas (95% of tumors are found at the time of surgery; 5-year cure is 40% when all are removed.) Second surgeries are worth considering if there is radiologic evidence of new or growing tumors and resection may prolong life span (4).
- Total gastrectomy is rarely indicated.
- In MEN1, parathyroidectomy, by lowering calcium, may also decrease acid production and decrease antisecretory drug use. Gastrinomas in MEN1 are generally small, benign, and multiple, and surgery is not usually curative in this situation.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Titrate medication to symptom control.
Appropriate surveillance postoperatively to look for metastasis

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Longitudinal follow-up to evaluate for metastases. Reoperation may be considered (4).
- Titrate medical therapy to control symptoms.
- Advise patients of potential danger of stopping antisecretory treatment. Rare cases have been reported of severe adverse outcomes within 2 days of stopping PPIs (5)[B]. Gastric acid analysis can help guide medical therapy to maintain basal gastric acid output at <10 mEq/hr (<2 mEq/hr if patient has complications such as perforation or esophagitis).

**DIET**
Restrict foods that aggravate symptoms.

**PATIENT EDUCATION**
Inform patients as to the nature of disease and prognosis.

**PROGNOSIS**
- Overall survival rate: 5 to 10 years: 69–94%
- The prognosis improves with complete surgical removal of the tumor.
- If liver metastasis is present on initial surgery, 5-year survival is 30–40%; 10-year survival is 25%.
- Mortality is directly related to liver metastasis, tumor size, and presence of pancreatic tumors.

**COMPLICATIONS**
- Complications of peptic ulcer disease (e.g., bleeding, perforation, obstruction)
- 2/3 of gastrinomas are malignant with metastasis.
- Paraneoplastic phenomena (e.g., production of ACTH with resulting Cushing syndrome) is possible.
- Decrease in vitamin B$_{12}$ levels is possible with long-term PPI use.

**REFERENCES**
ADDITIONAL READING

CODES

ICD10

E16.4 Increased secretion of gastrin

CLINICAL PEARLS

- Consider Zollinger-Ellison syndrome if peptic ulcers recur or if unusually high doses of PPI are needed to control symptoms.
- Abdominal pain and diarrhea should be totally controllable with adequate medical treatment.
- ~25–30% of cases of ZES occur in association with MEN1.
- Once ZES is diagnosed, search for gastrinomas in the head of the pancreas and the first or second portion of the duodenum.
- PPIs heal ZES ulcers. Patients should anticipate lifelong therapy.

AST elevation, A-12
Asthma, 84–85
    chronic cough in, 188–189
    exacerbation, pediatric acute, A-13
    in-flight emergency, 26–27
    initial treatment of, A-14
    maintenance treatment of, A-15
Asymmetric oligoarthritis, 74
Asymptomatic bacteriuria (ASB), 104–105
Asymptomatic inflammatory prostatitis, 826
Asymptomatic microscopic hematuria (AMH), 442–443
Ataxia, A-16
Ataxia-telangiectasia, 132
Atelectasis, 86–87
Atherosclerosis
    and carotid stenosis, 160–161
    and coronary artery disease, 226–227
    and hypercholesterolemia, 494–495
    and mild cognitive impairment, 657
and myocardial infarction, 12, 14
and peripheral arterial disease, 762–763
and unstable angina, 12
Athlete’s foot (tinea pedis), 532, 994–995
Atopic dermatitis, 272–273, 370
Atrial fibrillation (AFib), 88–89
Atrial flutter (AFlutt), 88–89
Atrial septal defect (ASD), 90–91
At-risk drinking, 28–29
Atrophic gastritis, 384–385
Atrophic lichen planus, 596
Attention deficit/hyperactivity disorder (ADHD)
  adult, 92–93
  pediatric, 94–95
Attenuated familial adenomatous polyposis, 206
Atypical absence seizures, 914
Atypical angina, 226
Atypical autism, 98–99
Atypical mole (dysplastic nevus) syndrome, 96–97, 632–633
AUB. See Abnormal uterine bleeding
Auditory (eustachian) tube dysfunction, 356–357
Aura, with migraine, 430
Autism spectrum disorders, 98–99
Autistic disorder, 98–99
Autoeczematization. See Id reaction
Autoimmune hepatitis, 196–197
Autoimmune neuropathy, acute. See Guillain–Barré syndrome
Autoimmune thyroid disease, 414, 530–531, 990
Autoimmune uveitis, 1048
Autonomic neuropathy, diabetic, 288
Autonomy, and capacity (competence) determination, 152–153
Autosomal dominant polycystic kidney disease (ADPKD), 788–789
Autosomal recessive polycystic kidney disease (ARPKD), 788–789
Axial inflammatory spondyloarthropathy, 56
Ayurvedic medicine, 208–209
Azotemia, A-17

B
Babesia, 100
Babesiosis, 100–101
Baby blues, 266
Bacillus cereus, 374–375
Back pain, low, 102–103
  chronic, A-74
Bacteremia
  with meningitis, 640
  without meningitis, 640
Salmonella, 898–899
Bacterial arthritis. See Septic arthritis
Bacterial croup. See Bacterial tracheitis
Bacterial diarrhea
  acute, 290–291
  chronic, 292–293
Bacterial endocarditis, 326–327
Bacterial food poisoning, 374–375, 898–899
Bacterial meningitis, 636–637
Bacterial parotitis, 746–747
Bacterial peritonitis, 764–765
Bacterial pneumonia, 780–781
Bacterial prostatitis, 826–827
Bacterial sinusitis, 928–929
Bacterial tracheitis, 1006–1007
Bacterial vaginosis, 584, 861, 1056–1057
Bacteriuria, asymptomatic, 104–105
Baker (popliteal) cyst, 798–799
Balanitis, 106–107, 150
Balanitis xerotica obliterans (BXO), 106–107
Bamboo spine (ankylosing spondylitis), 56–57
Barbiturate abuse, 302–303
Bariatric surgery, 707
  vitamin deficiency after, 1076–1077
Barlow syndrome. See Mitral valve prolapse
Barrett esophagus, 108–109, 386–387
Barrier methods, of contraceptives, 218–219
Basal cell acanthoma. See Seborrheic keratosis
Basal cell carcinoma
  skin, 110–111
  vulvar, 1082
Basal cell papilloma. See Seborrheic keratosis
Basaloid SCC, 946
Basedow disease. See Graves disease
Basilar migraine, 430
BCVI. See Blunt cerebrovascular injury
Becker muscular dystrophy (BMD), 678–679
Bed bugs, 80–81, 112–113
Bed sore (pressure ulcer), 816–817
Bed wetting (enuresis), 114–115, 334–335
Behavioral problems, pediatric, 114–115
Behavioral therapy, 230–231
Behçet syndrome, 1060–1061
Bell palsy, 116–117
Benign acanthokeratoma. See Seborrheic keratosis
Benign hypertension. See Essential hypertension
Benign paroxysmal positional vertigo (BPPV), 574–575, 1068–1069
Benign prostatic hyperplasia (BPH), 824–825
Benign rolandic epilepsy, 916–917
Benzodiazepines, abuse of, 302–303
Beriberi, 1076
Bernard–Horner syndrome. See Horner syndrome
Bernard syndrome. See Horner syndrome
Besnier–Boeck disease. See Sarcoidosis
β-Thalassemia, 980–981
Biceps tendinopathy, 926–927
Bickerstaff encephalitis, 420
Bicycle accidents, 552–553
Biliary cirrhosis, 196–197
Biliary cirrhosis, primary, 196–197
Bilirubin
   elevated levels of, A-57
   in Gilbert disease, 396–397
Billowing mitral cusp syndrome. See Mitral valve prolapse
Binge eating disorder, 58, 142–143
Binswanger disease. See Vascular dementia
Biologically based therapies, 208
Biotin deficiency, 1077
Biphenotypic acute leukemia, 588
Bipolar disorder
   bipolar I disorder (BP-I), 118–119
   bipolar II disorder (BP-II), 120–121
   counseling for, 231
   psychosis in, 846
Birth, preterm, 818–819, 1053
Birth control (contraception), 218–219, A-31–A-32
Bites
  animal, 122–123, 168, 169, 858–859
  arthropod, 80–81
  bed bug, 80–81, 112–113
  human, 122–123, 168, 169
Bitter orange, 209
B–K mole syndrome, 96–97
Black cohosh, 209
Bladder cancer, 124–125
Bladder pain syndrome. See Interstitial cystitis
Bladder stones, 1040–1041
Bleeding
  abnormal uterine, 2–3, 646–647
  diverticular, 296–297
  epistaxis, 342–343
  hemorrhoidal, 448–449
  rectal, A-99
  upper gastrointestinal, A-54
  vaginal
    abnormal, A-113
    during pregnancy, 1052–1053
Bleeding gums, 398–399. See also Gingivitis
Blenorrhreal arthritis, idiopathic. See Reactive arthritis
Blepharitis, 214, 464
Blood
  in urine (hematuria), 442–443
  in vomit (hematemesis), A-54
Blood loss, chronic, anemia of. See Iron deficiency anemia
Blood pressure
  high (See Hypertension)
  low (See Hypotension)
Blood urea nitrogen (BUN), elevated levels of, A-17
Bloody show of labor, 1052
Blue cohosh, 209
Blunt cerebrovascular injury (BCVI), 176–177
BMD. See Becker muscular dystrophy
Body lice, 752–753
Body surface area (BSA), in burns, 146
Boeck sarcoid. See Sarcoidosis
Boils. See Furunculosis
Bone infection (osteomyelitis), 720–721
Bone mineral density, 362–363, 722–723
Borderline personality disorder (BPD), 126–127, 846
Bordetella parapertussis, 766
Bordetella pertussis, 140, 766
Borrelia burgdorferi, 608–609
Botryoid rhabdomyosarcoma, 884–885
Botulism, 374–375
Bowen disease, 946
BPD. See Borderline personality disorder
BPH. See Benign prostatic hyperplasia
BPPV. See Benign paroxysmal positional vertigo
Bradykinin-mediated angioedema, 52–53
Brain injury, traumatic, 128–129
  mild
  concussion, 128–129, A-27
  postconcussion syndrome, 128–129, 802–803
  sideline evaluation, A-27
  moderate, 128–129
  severe, 128–129
BRCA1/BRCA2 genes, 132, 304
Breast
  fibrocystic changes of, 366–367
  inflammation of (mastitis), 130–131, 620–621
  male, hypertrophy of (gynecomastia), 422–423
  Paget disease of, 132
  palpable mass in, A-83
Breast abscess, 130–131, 620–621
Breast cancer, 132–133, 584
  ductal carcinoma in situ, 132, 304–305
  lymphedema after treatment, 612–613
Breast discharge, 380–381, 504
Breastfeeding, 134–135
  and allergic rhinitis, 888
  and bronchiolitis, 138
  and contraception, 219
  and infantile colic, 201
  and mastitis, 135, 620–621
  and otitis media, 726
  and postpartum depression, 266–267
  and pyloric stenosis, 856
Breast milk jaundice, 135
Breast pain (mastalgia), 366
Breast stimulation, 209
Brill–Zinsser disease. See Typhus fevers
Brock syndrome, 86
Broken heart syndrome. See Transient stress cardiomyopathy
Bronchiectasis, 136–137
Bronchiolitis, 138–139, 872–873
Bronchitis
  acute, 140–141
  chronic, 192–193
Bronze diabetes. See Hemochromatosis
Brugada syndrome, 156
Bruxism. See Temporomandibular joint disorder
Buccal cellulitis, 168
Bulimia nervosa, 142–143
Bullous impetigo, 536–537
Bullous lichen planus, 596
Bullying
  cyberbullying, 552
  traditional, 552
BUN (blood urea nitrogen), elevated levels of, A-17
Bunion, 144–145, 652–653
Burning vulva syndrome, 838–839
Burns, 146–147
  ocular chemical, 710–711
Bursitis
  definition of, 1020
  knee pain with, 572–573
  pes anserine, 148–149, 572
  shoulder pain with, 926–927
  subacromial, 926
  trochanteric, 1020–1021
Butcher warts, 1090
BXO. See Balanitis xerotica obliterans

C
Cachexia, diabetic, 288
CAE. See Childhood absence epilepsy
Calcium
  hypercalcemia, 1040, A-58
  hypercalciuria, 1040–1041
hypocalcemia, 1074–1075, A-66
Calcium oxalate stones, 1040–1041
Calcium pyrophosphate dihydrate (CPPD) crystal deposition, 842–843
Calculi
  gallstones, 186–187, 232
  renal, 232, 442–443, 492–493
  salivary gland, 746, 896–897
  urinary tract, 1040–1041
California encephalitis virus, 638
California poppy, 209
Calluses, 224–225
Campylobacter, 232, 864–865
Campylobacter jejuni, 290–291, 374–375
CA-MRSA. See Community-acquired methicillin-resistant Staphylococcus aureus
Canalicular cryptorchidism, 236–237
Cancer
  anal, 388
  bladder, 124–125
  breast, 132–133, 584
    ductal carcinoma in situ, 132, 304–305
    lymphedema after treatment, 612–613
  cervical, 4–5, 178–179, 584, 810–811
  colon (colorectal), 204–205
  endometrial, 328–329
  esophageal, 108–109, 386–387
  kidney, Wilms tumor, 1092–1093
  leukemia
    acute lymphoblastic, in adults, 586–587
    acute myeloid, 588–589, 684–685
    chronic lymphocytic, 590–591
    chronic myelogenous, 592–593, 686–687
  liver (HCC, hepatoma), 458–459
  lung, 602–603
  lymphoma, Hodgkin, 480–481
  medical marijuana for chemotherapy side effects in, 630
  multiple myeloma, 672–673
  ovarian, 584, 730–731
  pancreatic, 736–737
  prostate, 822–823
  skin
    actinic keratosis and, 568–569
atypical mole (dysplastic nevus) syndrome and, 96–97, 632–633
basal cell carcinoma, 110–111
melanoma, 96–97, 632–633, 1054, 1082
squamous cell, 946–947
testicular, 974–975
thyroid, 988–989
vaginal, 1054–1055
vulvar, 1082–1083
Cancer-associated vasculitis, 1060–1061
Candida albicans, 150, 1056
Candida glabrata, 1056
Candidal endocarditis, 326
Candidal folliculitis, 370
Candidal onychomycosis, 712–713
Candidal otitis externa, 724–725
Candidal paronychia, 150, 744
Candidal parotitis, 746
Candidal pyelonephritis, 854
Candidiasis
  mucocutaneous, 150–151
  vulvovaginal, 150–151, 1056–1057, 1089
Canker sore (aphthous ulcer), 1030–1031
Cannabis
  marijuana use disorder, 618–619, 954–955
  medical marijuana, 630–631
CAP. See Community-acquired pneumonia
Capacity Assessment Tool (CAT), 153
Capacity (competence) determination, 152–153
Capillary hemangioma, lobular, 416–417
CAPS. See Catastrophic APS
Carbon monoxide poisoning, 154–155
Carcinoid syndrome (neuroendocrine tumor), chronic diarrhea with, 292–293
Carcinoid tumor, lung, 602
Carcinoma in situ (CIS)
  ductal (breast), 132, 304–305
  vaginal, 1054–1055
Carcinosarcoma
  endometrial, 328
  ovarian, 730
Cardiac arrest, in-flight, 26–27
Cardiac arrhythmia, A-18. See also specific types
in-flight emergency, 26–27
long QT interval-related, 600–601
palpitations and, A-84
potassium levels and, 498–500, 522–523
syncope with, 960–961
Cardiac risk, preoperative reduction of, 812–813, A-93
Cardiomyopathy, 156–157
dilated, 156–157
end-stage, 156–157
hypertrophic, 156–157
ischemic, 156–157
peripartum, 156
restrictive, 156–157
temporary stress, 1012–1013
Caries, dental, 258–259
Carney complex, 238, 774
Carotid artery dissection, 176
Carotid sinus hypersensitivity (CSH), 158–159, 960–963
Carotid sinus massage (CSM), 158–159
Carotid sinus syndrome (CSS), 158–159
Carotid stenosis, 160–161
Carpal tunnel syndrome, 162–163
Car sickness. See Motion sickness
Cascara sagrada, 209
Catamenial cyclic vomiting syndrome, 242
Cataplexy, 688–689
Cataracts, 164–165
Catarrhal fever, acute. See Influenza
Catastrophic APS (CAPS), 60–61
Cat bites, 122–123, 858–859
Catecholaminergic polymorphic ventricular tachycardia (CPVT), 156
Causalgia, 210–211
CCS. See Central cord syndrome
CD. See Crohn disease
C. diff. See Clostridium difficile infection
Celiac disease, 166–167, 292–293
Celiac sprue. See Celiac disease
Cellulitis, 168–169
abdominal wall, 168
buccal, 168
erysipelas, 346–347
facial, 168
necrotizing, 168–169
orbital, 168, 170–171, 172
perianal, 168
periorbital, 168, 172–173
peritonsillar, 168
postpartum, 332–333
Celtic disease. See Dupuytren contracture
Central cord syndrome (CCS), 176–177
Cerebral edema, high-altitude, 34–35, 69
Cerebral infarct. See Stroke
Cerebral palsy (CP), 174–175
Cerebrospinal fluid (CSF), in normal pressure hydrocephalus, 490–491
Cerebrovascular accident. See Stroke
Cervarix vaccine, 178. See also Human papillomavirus (HPV) vaccine
Cervical dysplasia, 4–5
Cervical ectopic pregnancy, 318–319
Cervical hyperextension injuries, 176–177, A-19–A-20
Cervical intraepithelial neoplasia (CIN), 4–5, 179, 811
Cervical (uterine) malignancy, 4–5, 178–179, 584, 810–811
Cervical rib syndrome. See Thoracic outlet syndrome
Cervical strain/sprain, 176–177
Cervical sympathetic syndrome. See Horner syndrome
Cervicitis
chlamydial, 184–185
reactive arthritis, 864–865
CF. See Cystic fibrosis
CFRD. See Cystic fibrosis-related diabetes
Chaparral, 209
Character disorder. See Personality disorders
Character pathology. See Personality disorders
Charcot–Marie–Tooth disease, 698
Cheilitis, angular, 150
Cheiropompholyx. See Dyshidrosis
Chemical burns, ocular, 710–711
Chemotherapy, medical marijuana for side effects of, 630
Chest pain, A-21
aortic valvular stenosis and, 64–65
chest wall (costochondritis), 228–229
in-flight emergency, 26–27
noncardiac, 226
non-ST-segment elevation MI, 12–13, 226
stable angina, 226–227
ST-segment elevation MI, 14–15, 226
transient stress cardiomyopathy, 1012–1013
unstable angina, 12–13, 226
Chickenpox (varicella zoster), 180–181, 464–465, 638
Chickenpox (varicella zoster) vaccine, 68, 180
Chilblains, 376
Child abuse, 182–183, 200, 201, A-22
Childhood absence epilepsy (CAE), 914–915
Childhood autism, 98–99
Childhood disintegrative disorder, 98–99
Child maltreatment. See Child abuse
Child neglect, 182–183
Chinese medicine, 208–209
Chiropractic therapy, 208
Chlamydia infections
  acute bronchitis, 140
cervicitis, 184–185
conjunctivitis, 214–215
endocarditis, 326
epididymitis, 338
gay men and, 388
lesbians and, 584
pelvic inflammatory disease, 184–185, 754–755
prepubescent vulvovaginitis, 1088–1089
prostatitis, 826
rape and, 861
reactive arthritis, 184, 864–865
sexually transmitted, 184–185, 861
urethritis, 184–185, 1034–1035
Chlorosis. See Iron deficiency anemia
Cholangitis, primary sclerosing, 232
Cholelithiasis, 186–187, 232
Cholesterol, elevated levels of, 494–495
Cholinergic urticaria, 1042–1043
Chondrocalcinosis. See Pseudogout
Chondrocostal junction syndrome. See Costochondritis
Chondroitin sulfate, 209
Chorionic villus sampling (CVS), 810
Chorioretinitis, 465, 468, 1048–1049
Choroiditis, 1048–1049
Christmas disease. See Hemophilia
Chronic abdominal pain, A-2
Chronic bacterial prostatitis, 826–827
Chronic bronchitis, 192–193
Chronic cough, 188–189
Chronic cystic mastitis. See Fibrocystic changes of breast
Chronic diarrhea, 292–293, A-40
Chronic disease, anemia of, 44–45
Chronic fatigue syndrome (CFS), 680–681
Chronic headache, A-52
Chronic heart failure, 438–439
Chronic hypertension. See Essential hypertension
Chronic inflammatory demyelinating polyneuropathy (CIDP), 288–289
Chronic insomnia, 554–555
Chronic interstitial nephritis (CIN), 560–561
Chronic joint pain and stiffness, A-23
Chronic kidney disease (CKD), 190–191
Chronic lymphocytic leukemia (CLL), 590–591
Chronic migraine, 430–431
Chronic myelogenous leukemia (CML), 592–593, 686–687
Chronic obstructive pulmonary disease (COPD), 192–193, 220–221, A-24–A-25
in-flight emergency, 26–27
Chronic otitis externa, 724–725
Chronic otitis media, 726–727
Chronic pain, A-82
abdominal, A-2
definition of, 194
joint, A-23
low back, A-74
management of, 194–195
medical marijuana for, 630
pelvic, 826
Chronic papulopustular facial dermatitis. See Perioral dermatitis
Chronic parotitis, 746–747
Chronic pelvic pain syndrome (chronic prostatitis), 826
Chronic prostatitis/chronic pelvic pain syndrome, 826
Chronic pyelonephritis, 854–855
Chronic sycosis barbae. See Pseudofolliculitis barbae
Chronic tension–type headache, 432–433
Chronic thromboembolic pulmonary hypertension (CTEPH), 848
Chronic urticaria, 1042–1043
Chronic venous insufficiency (CVI), stasis dermatitis with, 280–281
Churg–Strauss disease, 404, 1060–1061
Cicatricial alopecia, 32–33
Cicatrisation, 86
Cigarette smoking, 700–701
Circadian rhythm sleep disorders (CRSD), 554–555, 934–935
Cirrhosis, 196–197, A-26
  ascites with, 82–83, 196–197
  encephalopathy with, 196, 197, 454–455
  esophageal varices with, 196–197, 352–353
  NASH, 196, 702–703
  peritonitis with, 764–765
  portal hypertension with, 82–83, 352–353, 800–801
CJD. See Creutzfeldt–Jakob disease
CKD. See Chronic kidney disease
Clark nevi syndrome, 96–97
Claw toe, 424–425, 652
Clear cell carcinoma
  endometrial, 328
  ovarian, 730–731
  vaginal, 1054
Clinically isolated syndrome (CIS), in multiple sclerosis, 674
Closed-angle glaucoma, primary, 400–401
Clostridium botulinum, 374–375
Clostridium difficile infection (C. diff), 198–199, 232, 290–291, 292
Clostridium perfringens, 374–375
Club drugs, 954
Cluster headache, 428–429
CMD. See Congenital muscular dystrophies
CMV. See Cytomegalovirus
Coagulation disorders
  antiphospholipid antibody syndrome, 60–61
  antithrombin deficiency, 850, 984
  Factor V Leiden, 248, 358–359, 850, 984
  hemophilia, 446–447
  protein C deficiency, 828–829, 850, 984
  protein S deficiency, 830–831, 850, 984
  prothrombin 20210 (mutation), 248, 834–835, 850, 984
  thrombophilia and hypercoagulable states, 984–985
  von Willebrand disease, 1080–1081
Coelomic metaplasia, 330
Cogan syndrome, 1060–1061
Cognitive-behavioral therapy (CBT), 208–209, 230–231
Cognitive impairment
  chronic fatigue syndrome and, 680
  mild, 36, 656–657
  reversible, 656
Cold agglutinin-positive pneumonia. See Pneumonia, mycoplasma
Cold exposure
  and frostbite, 376–377
  and hypothermia, 528–529
Cold sores (HSV-1), 466, 468–469
Cold urticaria, 1042–1043
Colic, infantile, 200–201
Colitis
  ischemic, 202–203
  ulcerative, 204, 205, 232–233, 292–293, 1032–1033
Colon (colorectal) cancer, 204–205
Colonic polyps, 206–207
Coma, hepatic or liver. See Hepatic encephalopathy
Combination fracture, 948
Common warts, 1090–1091
Communicating hydrocele, 488
Community-acquired methicillin-resistant Staphylococcus aureus (CA-MRSA), 654–655
Community-acquired pneumonia (CAP), 780–781
Competence (capacity) determination, 152–153
Complementary and alternative medicine, 208–209
Complementary medicine, 208
Complete abortion, 658
Complex regional pain syndrome (CRPS), 210–211
Complicated diverticulitis, 296–297
Complicated urinary tract infection, 1038–1037
Compression atelectasis, 86–87
Concussion, 128–129
  postconcussion syndrome after, 128–129, 802–803
  sideline evaluation, A-27
Condom, 218–219, 388–389
Conductive hearing loss (CHL), 434–435
Condylomata acuminata (genital warts), 4–5, 212–213, 1090–1091
Confusional state, acute. See Delirium
Congenital adrenal hyperplasia, hirsutism in, 476–477
Congenital cataract, 164–165
Congenital hernia, 462–463
Congenital megacolon (Hirschsprung disease), 216
Congenital muscular dystrophies (CMD), 678–679
Congenital rubella syndrome, 626–627
Congenital toxoplasmosis, 1004–1005
Congestive heart failure, differential diagnosis of, A-28
Conjunctivitis
  acute, 214–215
  adenoviral, 214–215
  gonococcal, 410–411
  reactive arthritis, 864–865
Consent, capacity (competence) and, 152–153
Constipation, 216–217
  diagnosis and treatment, adult, A-29
  in elderly, 392
  functional (encopresis), 114–115, 324–325
  irritable bowel syndrome and, 216, 562–563
  primary, 216
  secondary, 216
  treatment, pediatric, A-30
Contact dermatitis, 274–275
Contact urticaria, 1042
Contraception, 218–219, A-31–A-32
Contracture, Dupuytren, 306–307
Convulsion. See Seizure disorders
Cooley anemia. See Thalassemia
COPD. See Chronic obstructive pulmonary disease
Copper-bearing IUD, 218–219
Copper bracelets, 209
Corn(s), 224–225
Corneal abrasion and ulceration, 214, 222–223
Corneal hysteresis, 402
Coronary artery disease, 226–227, 392
  hypertriglyceridemia and, 516–517
  metabolic syndrome and, 650–651
  risk of in-flight emergency, 26
Coronary syndromes, acute. See Acute coronary syndromes
Cor pulmonale, 220–221
Cortical spreading depression, 430
Corticotroph adenoma, 774–775
Costochondritis, 228–229
Costoclavicular syndrome. See Thoracic outlet syndrome
Costosternal syndrome. See Costochondritis
Cough, chronic, 188–189
Cough hypersensitivity syndrome, 188
Counseling, 230–231
   travel medicine, approach to, 68–69
Cowden syndrome, 132, 206
Coxsackie virus A and B, 638
CP. See Cerebral palsy
CPPD. See Calcium pyrophosphate dihydrate (CPPD) crystal deposition
Crabs. See Pediculosis
Cradle cap, 278–279
Cramps, menstrual. See Dysmenorrhea
Cranberry, and urinary health, 1036–1037
Craniosacral therapy, 208
CREST syndrome, 910
Creutzfeldt–Jakob disease (CJD), 254–255
Crohn disease, 232–233
   chronic diarrhea in, 292–293
   colon cancer risk in, 204, 205
   ulcerative colitis versus, 232
Croup, 234–235, 578–579, 625, 1006–1007
CRPS. See Complex regional pain syndrome
Crying, excessive, colic and, 200–201
Cryoglobulin-associated glomerulonephritis, 404–405
Cryoglobulinemic vasculitis, 1060–1061
Cryptorchidism, 236–237, 974
Crystal arthropathies, 412–413, 842–843
CSH. See Carotid sinus hypersensitivity
CSM. See Carotid sinus massage
CSS. See Carotid sinus syndrome
CTEPH. See Chronic thromboembolic pulmonary hypertension
Cupping, 209
Cushing disease, 238–239
Cushing syndrome, 238–239, 476
Cutaneous arteritis, 1060–1061
Cutaneous drug reactions, 240–241, 596
Cutaneous horn, 946
Cutaneous leukocytoclastic angiitis, 1060–1061
Cutaneous squamous cell carcinoma, 946–947
CVA. See Stroke
Cyberbullying, 552
Cyclic vomiting syndrome, 242–243
Cycloplegia, 1049
Cyst(s)
  breast, 366–367
  ovarian, ruptured, 732–733
  polycystic kidney disease, 788–789
  polycystic ovary syndrome, 790–791
  popliteal (Baker), 798–799
Cystic fibrosis, 244–245
  bronchiectasis in, 136–137
  diarrhea in, 292
Cystic fibrosis-related diabetes (CFRD), 244
Cystine stones, 1040–1041
Cystitis, 1038–1037. See also Urinary tract infection
  interstitial, 558–559
Cytomegalovirus (CMV), HIV-related, 478–479
Cytomegalovirus (CMV) meningitis, 638

D
Dacryocystitis, 214
Daytime enuresis, 334–335
Daytime sleepiness, excessive, 688–689
DBT. See Digital breast tomosynthesis
DCIS. See Ductal carcinoma in situ
Decompensated heart failure, acute, 436–437
Decubitus ulcer, 816–817
Deep vein thrombophlebitis (thrombosis) (DVT), 248–249, 984
  diagnosis and treatment, A-33–A-34
  in-flight emergency, 26–27
  pulmonary embolism with, 248–249, 850
Degenerative disc disease, 102–103, 940
Degenerative joint disease. See Osteoarthritis
Dehydration, 250–251
  acute diarrhea and, 290–291
  cyclic vomiting syndrome and, 242–243
  oral rehydration therapy for, 250–251
  pediatric, A-35
Delayed ejaculation, 320–321
Delayed pressure urticaria, 1042–1043
Delirium, 252–253, 392, A-36
  hyperactive, 252
  hypoactive, 252
  mixed, 252
  normal consciousness, 252
Delusional disorder, 846
Delusions, 846–847
Dementia, 254–255, A-37
  Alzheimer disease, 36–37, 152, 254–255
  capacity (competence) determination in, 152–153
  frontotemporal, 254–255
  HIV-related, 254–255
  Lewy body, 254–255
  normal pressure hydrocephalus, 490–491
  progression of MCI to, 656
  psychosis in, 846–847
  vascular, 254–257
Demodex folliculitis, 370
Demyelinating optic neuropathy. See Optic neuritis
Dental infection, 258–259
Depo-Provera, 218
Depression, 260–261
  adolescent, 262–263
  in bipolar I disorder, 118–119
  in bipolar II disorder, 120–121
  counseling for, 231
  in dementia, 254, 255, 257
  geriatric, 264–265, 392
  in LGBT persons, 389
  in menopause, 644
  in postconcussion syndrome, 802–803
  postpartum, 266–267
  in posttraumatic stress disorder, 804–805
  psychosis in, 846–847
  in seasonal affective disorder, 912–913
  suicide risk in, 260–265, 956–957
  treatment-resistant, 263, 268–269
Depressive episode, major, A-38
De Quervain tenosynovitis, 246–247
De Quervain thyroiditis, 514, 990–991

Dermatitis
  acute and recurrent hand (See Dyshidrosis)
  atopic, 272–273, 370
  contact, 274–275
  diaper, 150, 276–277
  dyshidrosis, 308–309
  exfoliative, 240–241
  lichen simplex chronicus, 598–599
  perioral, 370
  seborrheic, 278–279
  stasis, 280–281, 532
  vaginitis, 1056–1057

Dermatitis congelationis. See Frostbite

Dermatitis contusiformis. See Erythema nodosum

Dermatitis herpetiformis, 270–271

Dermatitis venenata. See Dermatitis, contact

Dermatographism, 1042–1043

Dermatomyositis, 796–797

Dermatophytes, 712–713, 992–995

Dermatophytid. See Id reaction

Dermatosis, acute febrile neutrophilic (Sweet syndrome), 240–241

Dermatosis papulosa nigra, 570

Desire, sexual, disorders of, 924–925

Desmoplastic melanoma, 632

Desquamation of interdigital spaces. See Dyshidrosis

Desquamative inflammatory vaginitis, 1056

Detoxification programs, 303

Diabetes mellitus
  chronic diarrhea in, 292–293
  cystic fibrosis-related, 244
  gestational, 810–811
  glucose intolerance (prediabetes) and, 408–409
  granuloma annulare in, 414
  hypoglycemia in, 518–519
  kidney disease in, 190–191
  metabolic syndrome and, 650–651
  type 1, 282–283
  type 2, 284–285
  type 2, treatment, A-112

Diabetic amyotrophy, 288
Diabetic cachexia, 288
Diabetic ketoacidosis, 286–287, A-39
Diabetic nephropathy, 692
Diabetic neuropathy/polyneuropathy, 288–289, 698–699
Diabetic retinopathy, 878–879
Dialectical behavior therapy (DBT), 230–231
Diaper dermatitis, 150, 276–277
Diaphragm (contraceptive), 218–219
Diarrhea
  acute, 290–291
  celiac disease and, 166–167, 292–293
  chronic, 292–293, A-40
  Clostridium difficile, 198–199, 232, 290–291, 292
  Crohn disease and, 232–233, 292–293
dehydration in, 250–251
  giardiasis, 290–291, 292, 394–395
  irritable bowel syndrome and, 562–563
  lactose intolerance and, 292–293, 576–577
oral rehydration for, 250–251
  overflow, 538–539
  traveler’s, 68–69, 290–291, 374
  ulcerative colitis and, 292–293, 1032–1033
Dietary protein sensitivity syndrome. See Food allergy
Diethylstilbestrol (DES) exposure, 1050–1051
Dietl crisis, 492
Diffuse interstitial lung disease, 294–295
Digital breast tomosynthesis (DBT), 304
Digital gaming disorder, 382–383
Digital stenosing tenosynovitis, 1018–1019
Dilated cardiomyopathy, 156–157
Dilatory eustachian tube dysfunction, 356
Diminished ovarian reserve (DOR), 546
Disc disorders or degeneration, 102–103, 940
Discharge, breast, 380–381, 504
Discoid meniscus, 642
Disordered lactation. See Galactorrhea
Disruptive mood dysregulation disorder (DMDD), 262
Dissection, carotid and vertebral artery, 176
Distal interphalangeal joint (DIJ), psoriatic arthritis of, 74
Diversion, of medication, 302–303
Diverticular bleeding, 296–297
Diverticular disease, 296–297
Diverticulitis
  acute, 296–297
  complicated, 296–297
  uncomplicated, 296–297
Diverticulosis, 296–297
Dizziness, 1066–1067, A-41. See also Vertigo
DMD. See Duchenne muscular dystrophy
DMDD. See Disruptive mood dysregulation disorder
DNI (do not intubate) orders, 25
DNR (do not resuscitate) orders, 25
DNS. See Dysplastic nevus syndrome
Dog bites, 122–123, 169, 858–859
Domestic abuse, elder, 322–323
Domestic violence, 298–299, 389, 482, 552–553, 584–585, 810
DOR. See Diminished ovarian reserve
Down syndrome (DS), 300–301, 556–557
DPOA. See Durable power of attorney
DRESS syndrome, 240–241
Drowning, 552–553
  nonfatal, 704–705
Drug (substance) abuse, 954–955
  alcohol, 28–31, 231, 954–955
  anabolic steroid, 954
  counseling for, 231
  gay health, 388
  geriatric, 392
  homelessness with, 482
  marijuana (cannabis), 618–619, 954–955
  nicotine, 700–701, 954–955, 1000–1001
  opioid, 302–303, 954–955
  prescription drug, 302–303, 954–955
Drug-associated antineutrophil cytoplasmic antibodies (ANCA)-associated vasculitis, 1060–1061
Drug-induced immune complex vasculitis, 1060–1061
Drug-induced lichen planus, 596
Drug-induced lupus, 604
Drug-induced psychosis, 846
Drug-induced pulmonary hypertension, 848
Drug-induced thyroiditis, 514–515, 990–991
Drug rash with eosinophilia and systemic symptoms (DRESS) syndrome, 240–241
Drug reactions, cutaneous, 240–241, 596
Dry beriberi, 1076
Dry eyes, in Sjögren syndrome, 930–931
Dry mouth, in Sjögren syndrome, 930–931
Duchenne muscular dystrophy (DMD), 678–679
Ductal carcinoma in situ (DCIS), 132, 304–305
Duct tape, for warts, 1091
Duhring–Brocq disease. See Dermatitis herpetiformis
Duhring disease. See Dermatitis herpetiformis
Duodenal ulcers, 756–757
Dupuytren contracture, 306–307
Dupuytren diathesis, 306–307
Durable power of attorney (DPOA), 24–25, 392
DVT. See Deep vein thrombophlebitis
Dysentery-associated Reiter syndrome, 864–865
Dyshidrosis, 308–309
Dyslipidemia
  granuloma annulare in, 414
  hypercholesterolemia, 494–495
  hyperlipidemia, A-60–A-62
  hypertriglyceridemia, 516–517, A-64
  metabolic syndrome, 650–651
Dysmenorrhea, 310–311, 330–331
Dysmyelopoietic syndrome. See Myelodysplastic syndromes
Dyspepsia, A-42
  functional, 314–315
Dysphagia, 316–317, A-43
Dysplastic nevus syndrome, 96–97, 632–633
Dyspnea
  atrial fibrillation/flutter and, 88
  transient stress cardiomyopathy and, 1012–1013
Dystonia, acute, 846

E
Ear infections
  mastoiditis with, 622–623
  otitis externa, 724–725
  otitis media, 726–727
  otitis media with effusion, 728–729
Early infantile autism, 98–99
Early pregnancy loss (miscarriage), 658–659, 1052–1053
Early to mid-childhood acne, 10
Eating, problem (“picky eaters”), 114–115
Eating disorders
  anorexia nervosa, 58–59
  binge eating, 58, 142–143
  bulimia nervosa, 142–143
  counseling for, 231
  female athlete triad, 362–363
  LGBT persons and, 389
  purging, 58, 142–143
Eaton agent pneumonia. See Pneumonia, mycoplasma
EBV. See Epstein–Barr virus
Echovirus, 638
E-cigarettes (vaping), 954, 1000–1001
Eclampsia, 806–807, 810
Ecthyma, 536–537
Ectodermosis erosiva pluriorificialis. See Stevens–Johnson syndrome
Ectopic cryptorchidism, 236–237
Ectopic gastric mucosal ulceration, 756–757
Eczema
  dyshidrotic, 308–309
  gravitational (See Stasis dermatitis)
  varicose (See Stasis dermatitis)
Eczematous otitis externa, 724–725
ED. See Erectile dysfunction
Edema
  angioedema, 52–53, 1042
  cerebral, high-altitude, 34–35, 69
  pulmonary, 868
    high-altitude, 34–35, 69
    noncardiogenic, 868
EDMD. See Emery–Dreifuss muscular dystrophy
Effusion
  otitis media with, 728–729
  pleural, 778–779
Egg allergy, 372–373
EGPA. See Eosinophilic granulomatosis with polyangiitis
Eisenmenger complex, 1064–1065
Eisenmenger syndrome, 90–91
Ejaculatory anhedonia, 320–321
Ejaculatory disorders, 320–321
Ejaculatory duct obstruction, 320–321
Elder abuse, 322–323, 393
Elderly
  depression in, 264–265, 392
  general principles of care, 392–393
  hearing loss in, 392, 434, 814–815, 998
  hypertension in, 512–513
  lesbian, 585
Ella, 219
Emboli, pulmonary, 248–249, 850–851, 984
  diagnosis, A-95
  in-flight emergency, 26–27
  treatment, A-96
Embryonal rhabdomyosarcoma, 884–885
Embryonic demise, 658
Emergency, in-flight, 26–27
Emergency contraception, 219
Emery–Dreifuss muscular dystrophy (EDMD), 678–679
Emotional abuse, 182–183
Emphysema, 86, 192–193
Encephalitis
  Bickerstaff, 420
  herpes, 468–469
  measles, 625
  meningitis with, 638
  mumps, 676–677
Encephalomyelitis, myalgic, 680–681
Encephalopathy
  hepatic, 196, 197, 454–455, 800–801
  Wernicke, 1076
Encopresis, 114–115, 324–325
Endemic typhus, 1028–1029
Endocarditis
  gonococcal, 410–411
  infective, 326–327
End-of-life care, 734–735
Endolymphatic hydrops. See Ménière disease
Endometrial cancer, 328–329
Endometriosis, 330–331
Endometritis, 332–333, 754
End-stage cardiomyopathy, 156–157
Energy availability, in female athlete triad, 362–363
Energy therapies, 208
Entamoeba histolytica, 290–291
Enteric-associated Reiter syndrome, 864–865
Enteric fever. See Typhoid fever
Enterobiasis. See Pinworms
Enterobius vermicularis, 772, 1088
Enterococcal bacteriuria, 104
Enterococcal endocarditis, 326–327
Enterococcal pyelonephritis, 854, 855
Enterovirus infections, meningitis, 638
Enthesitis-related arthritis, 72
Enthesopathy, definition of, 1020
Enuresis, 334–335
  daytime, 334–335
  nocturnal, 114–115, 334–335
  primary, 334
  secondary, 334
Environmental hazards, in travel, 69
Eosinophilic folliculitis, 370–371
Eosinophilic granulomatosis with polyangiitis (EGPA), 404, 1060–1061
Eosinophilic pustular folliculitis, 370–371
Ephedra, 209
Epicondylitis, 336–337
Epidemic parotitis. See Mumps
Epidemic typhus, 1028–1029
Epidermodysplasia verruciformis, 1090–1091
Epidermoid carcinoma. See Cutaneous squamous cell carcinoma
Epidermophyton floccosum, 992, 994
Epididymitis, 338–339
  chlamydial, 184–185, 338
  testicular involvement, 338
Epididymo-orchitis, 338
Epigastric hernia, 462–463
Epigastric pain syndrome (EPS), 314–315
Epilepsy, 918–919. See also Seizure disorders
Episcleritis, 214, 340–341, 908–909
Episodic tension–type headache, 432–433
Epistaxis, 342–343
Epithelial ovarian cancer, 730–731
Eponychia. See Paronychia
EPS. See Epigastric pain syndrome
Epstein–Barr virus (EBV) infection, 544–545, 638, 680–681
Erectile dysfunction (ED), 344–345
Erosive gastritis, 384–385
Erysipelas, 346–347
Erythema infectiosum, 748–749
Erythema migrans, 608–609
Erythema multiforme, 240–241, 348–349
Erythema nodosum, 350–351
Erythema multiforme. See Stevens–Johnson syndrome
Erythematotelangiectatic rosacea (ETR), 8
Erythrocytosis, A-44
Erythroderma, 240–241
Erythodermic psoriasis, 844
Erythroplasia of Queyrat, 946
Escalante syndrome. See Fragile X syndrome
Escherichia coli infections
  acute diarrhea, 290–291
  asymptomatic bacteriuria, 104
  breast, 130
  epididymitis, 338
  food poisoning, 374–375
  meningitis, 636–637
  parotitis, 746
  peritonitis, 764–765
  pyelonephritis, 854, 855
  urinary tract infection, 1038, 1036
  vulvovaginitis, 1088–1089
Esophageal adenocarcinoma, 108–109, 386–387
Esophageal dysphagia, 316–317
Esophageal ulcers, 756–757
Esophageal varices, 196–197, 352–353, 800–801
Esophagitis
  candidal, 150–151
  dysphagia in, 316–317
  GERD, 386–387
Esophagus, Barrett, 108–109, 386–387
Essential hypertension, 510–511
Essential thrombocythemia (ET), 686–687
Essential tremor syndrome, 354–355
Estradiol/levonorgestrel emergency contraception, 219
Estrogen-deficient vulvovaginitis, 1086–1087
Estrogen-progestin contraceptives, 218–219
ET. See Essential thrombocythemia
ETD. See Eustachian tube dysfunction
Etonogestrel implant, 219
Eustachian tube dysfunction (ETD), 356–357
Euvolemic hypernatremia, 500–501
Euvolemic hyponatremia, 524–525
Evidence-based approach, to chronic pain, 194–195
Exanthems, pediatric, A-88
Exanthem subitum. See Roseola
Excessive daytime sleepiness (EDS), 688–689
Exercise, 208–209
Exertional heat stroke, 440
Exfoliative dermatitis, 240–241
Exposure, in counseling, 230
Extensively drug-resistant (XDR) tuberculosis, 1023
External hemorrhoids, 40, 448–449
Extrinsic allergic alveolitis (EAA), 506–507
Exudative pleural effusion, 778
Exudative retinal detachment, 876–877
Eye(s)
  dry, 930–931
  red eye, A-100
Eye burns, chemical, 710–711
Eye infections. See also Conjunctivitis
Eyelid myoclonia, 914
Eyelids, granulated. See Blepharitis

F
Facial cellulitis, 168
Facial nerve compression (Bell palsy), 116–117
Facial paralysis, 116–117
Facioscapulohumeral muscular dystrophy (FSHMD), 678–679
Factitious diarrhea. See Laxative abuse
Factor VIII deficiency, 446–447
Factor IX deficiency, 446–447
Factor V Leiden, 248, 358–359, 850, 984
Failure to thrive (FTT), 360–361
Falls, 392, 552–553
False aneurysm, 50
Familial adenomatous polyposis (FAP), 204, 205, 206
Familial atypical multiple mole melanoma (FAMMM) syndrome, 96–97, 632
Familial hypercholesterolemia (FH), 494
Familial hypertension. See Essential hypertension
Family therapy, 230–231
Family violence. See Domestic violence
FAMM. See Familial atypical multiple mole melanoma (FAMMM) syndrome
FAP. See Familial adenomatous polyposis
Farmer’s lung, 506–507
FAS. See Fetal alcohol syndrome
Fasting hypoglycemia, 518, 520
Fatigue, A-45
    chronic, 680–681
Fatigue fracture, 948
Fatty liver disease, nonalcoholic, 702–703
Favre–Racouchot syndrome, 10
FCC. See Fibrocystic changes (FCC) of breast
Febrile mucocutaneous syndrome. See Stevens–Johnson syndrome
Febrile seizures, 918, 920–921
Febrile status epilepticus (FSE), 920–921
Fecal impaction, 538–539
Fecal incontinence, 538–539
    functional nonretentive, 324–325
Fecal soilage, 538
Female athlete triad, 362–363
Female infertility, 546–547
Female pattern hair loss, 32
Female sexual dysfunction. See Sexual dysfunction in women
Femoral hernia, 462–463
Fertility awareness methods, of contraception, 219
Fetal alcohol syndrome (FAS), 556
Fetal demise, 658
Fetal hiccups, 472
Fever
    in first 90 days of life, A-46
    seizures with, 918, 920–921
    of unknown origin (FUO), 364–365, A-47
FH. See Familial hypercholesterolemia
Fibrocystic changes (FCC) of breast, 366–367
Fibroids. See Uterine myomas
Fibroleiomyoma. See Uterine myomas
Fibromyalgia, 368–369
Fibromyoma. See Uterine myomas
Fibromyositis. See Fibromyalgia
Fibrosis, pulmonary, 852–853
idiopathic, 294–295, 852–853
nonidiopathic, 852
Fibrositis. See Fibromyalgia
Fibrous (Riedel) thyroiditis, 990–991
Fiessinger–Leroy–Reiter disease. See Reiter syndrome
Fifth disease, 748–749
FII A20210 mutation. See Prothrombin 20210 (mutation)
Filarial lymphangitis, 610–611
Filariasis, 610, 612
Filiform warts, 1090–1091
Fingernail onychomycosis, 712–713
Fingernail paronychia, 744–745
Fish allergy, 372–373
Fish oil, 209
Fissures, anal (fissure in ano), 40–41
Fistula
aortocaval, 50
aortoenteric, 50–51
perianal, 40
Fitz–Hugh–Curtis (FHC) syndrome, 754
Fixed drug eruptions, 240–241
Flat seborrheic keratosis, 570
Flat warts, 1090–1091
Floppy valve syndrome. See Mitral valve prolapse
Flu. See Influenza
FMS. See Fibromyalgia
Focal segmental glomerulosclerosis (FSGS), 692–693
Focal seizure disorder, 916–917
Follicular lichen planus, 596
Follicular psoriasis, 370
Follicular thyroid carcinoma, 988–989
Folliculitis, 370–371, 536
Folliculitis barbae, 370
Folliculitis barbae traumatica, 840–841
Folliculitis decalvans, 370
Food allergy, 372–373
Food poisoning
  bacterial, 374–375, 898–899
  Salmonella, 374–375, 898–899
Foreign body, in eye, 214
Fothergill neuralgia. See Trigeminal neuralgia
Fox-Fordyce disease, 370
Fox impetigo. See Impetigo
Fractures
  ankle, 54–55
  cervical, 176–177
  combination, 948
  fatigue, 948
  insufficiency, 948
  osteoporotic, 644–645, 722–723
  stress, 948–949
  tibial plafond, 54
Fragile X syndrome, 556–557
Freiberg infraction, 652
Frontotemporal dementia, 254–255
Frostbite, 376–377
Frostnip, 376
Frozen shoulder, 20–21, 926–927
FSE. See Febrile status epilepticus
FSGS. See Focal segmental glomerulosclerosis
FSHMD. See Facioscapulohumeral muscular dystrophy
FTT. See Failure to thrive
Functional dyspepsia, 314–315
Functional encopresis, 114–115, 324–325
Functional incontinence, 540–543
Functional nonretentive fecal incontinence (FNFI), 324–325
Fungal infections. See also specific infections
  cellulitis, 168
  folliculitis, 370–371
  id reaction, 532–533
  onychomycosis, 712–713
  otitis externa, 724–725
  parotitis, 746
  sinusitis, 928–929
  tinea capitis, 32, 33, 533, 992–993
tinea corporis, 533, 992–993

tinea cruris, 533, 992–993

tinea pedis, 532, 994–995

tinea versicolor, 996–997

FUO. See Fever, of unknown origin

Furunculosis, 378–379

FXS. See Fragile X syndrome

G

GAD. See Generalized anxiety disorder

Gait disturbance, A-48

   normal pressure hydrocephalus and, 490–491

Galactorrhea, 380–381, 504

Gallstones, 186–187, 232

Gaming disorder, Internet, 382–383

Gardasil 4 vaccine, 178

Gardasil 9 vaccine, 4, 178. See also Human papillomavirus (HPV) vaccine

Gardner syndrome, 206

GAS. See Group A β-hemolytic Streptococcus (GAS)

Gastric ulcers, 756–757

Gastrinoma, 1094–1095

Gastritis, 384–385

Gastroenteritis

   dehydration in, 250–251

   Salmonella, 898–899

Gastroesophageal reflux disease (GERD), 386–387

   Barrett esophagus in, 108–109, 386–387

   chronic cough in, 188–189

   diagnosis and treatment, A-49

   dysphagia in, 316–317

   infantile colic in, 200

   laryngitis in, 578–579

   scleroderma and, 910–911

Gastrointestinal bleeding, upper, A-54

Gastrointestinal candidiasis, 150

Gastrointestinal illness, in-flight emergency, 26–27

Gay health, 388–389

GBS. See Guillain–Barré syndrome

GDM. See Gestational diabetes mellitus

Gender-confirming surgery, 1008–1009

Gender-confirming therapy, 1008
Gender dysphoria, 1008
Gender identity, 1008
Gender nonconforming, 1008
Generalized anxiety disorder (GAD), 62–63
Generalized seizures, 918–919
Genetic hypertension. See Essential hypertension
Genital herpes (HSV-2), 466–469, 584
Genital pain
ejaculation, 320–321
vaginismus, 390–391, 924–925
vulvar, 1084–1085
Genital ulcers, A-50
Genital warts (condylomata acuminata), 4–5, 212–213, 1090–1091
Genito-pelvic pain/penetration disorder, 390–391, 924–925. See also Dyspareunia; Vaginismus
Genitourinary syndrome of menopause, 1086–1087
GERD. See Gastroesophageal reflux disease
Geriatric care, general principles of, 392–393
Geriatric depression, 264–265, 392
German measles (rubella), 626–627
Germ cell tumors (GCTs)
    ovarian, 730–731
testicular, 974–975
Gestational diabetes mellitus (GDM), 810–811
Giant cell arteritis (GCA), 70–71, 1060–1061
Giant cell thyroiditis, 990–991
Giant congenital nevus, 632
Giardia lamblia, 394
Giardiasis, 290–291, 292, 394–395
Gilbert disease, 396–397
Ginger, 208
Gingivitis, 398–399
    acute necrotizing ulcerative, 398–399, 1070–1071
    non-plaque-induced, 398
    plaque-induced, 398
Ginkgo biloba, 209
Glandular fever. See Infectious mononucleosis
Glaucoma
    acute, 214
    herpes infection and, 464–465
    primary closed-angle, 400–401
primary open-angle, 402–403
retinal detachment in, 876
Gleason score, 822–823
Glomerular proteinuria, 832–833
Glomerulonephritis
  acute, 404–405
  IgA nephropathy, 404–405
  membranoproliferative, 404–405, 406, 692
  pauci-immune, 404
  pauci-immune crescentic, 406
  postinfectious, 404–407, 536, 537
Glomerulosclerosis, focal segmental, 692
Glossopharyngeal syncope, 962
Glucosamine, 209
Glucose intolerance, 408–409
Glucose levels
  in chronic kidney disease, 191
  high (hyperglycemia)
    in diabetes mellitus type 1, 282–283
    in diabetes mellitus type 2, 284–285
    in diabetic ketoacidosis, 286–287
  low (hypoglycemia), A-67, A-67
    diabetic, 518–519
    fasting, 518, 520
    nocturnal, 518, 519
    nondiabetic, 520–521
    reactive, 520–521
  in metabolic syndrome, 650–651
“Glue ear.” See Otitis media with effusion
Gluten enteropathy. See Celiac disease
Gluten-free diet
  for celiac disease, 166–167
  for dermatitis herpetiformis, 270–271
Gluten-sensitive enteropathy (GSE), 270–271
Glycogen storage disease, 156
Goiter
  Graves disease, 418–419
  toxic multinodular, 514–515
Goldenseal, 209
Golfer’s elbow, 336–337
Gonadotropinoma, 774–775
Gonococcal (septic) arthritis, 78–79
Gonococcal cellulitis, 172
Gonococcal conjunctivitis, 214–215
Gonococcal endocarditis, 326
Gonococcal epididymitis, 338
Gonococcal infections, 410–411. See also specific infections
Gonococcal ophthalmia neonatorum, 214, 410–411
Gonococcal pelvic inflammatory disease, 410–411, 754–755
Gonococcal prostatitis, 826
Gonococcal urethritis, 410–411, 1034–1035
Gonococcal vulvovaginitis, 1088–1089
Gonorrhea, 410–411
  gay men and, 388
  lesbians and, 584
  rape and, 861
Goodpasture disease, 404
Goosefoot. See Pes anserine
Goosefoot (pes anserine), 148–149
Gout, 412–413
Granulated eyelids. See Blepharitis
Granulocytosis, A-51
Granuloma, pyogenic, 416–417
Granuloma annulare, 414–415
Granulomatosis
  eosinophilic, with polyangiitis, 404, 1060–1061
  with polyangiitis, 404
  Wegener, 294–295
Granulomatous lymphangitis, noninfectious, 610
Granulomatous mastitis, 620–621
Granulomatous perioral dermatitis. See Perioral dermatitis
Granulomatous thyroiditis, subacute, 990–991
Graves disease, 418–419, 514–515
Gravitational eczema. See Stasis dermatitis
Greater trochanteric pain syndrome (GTPS), 1020–1021
Grippe. See Influenza
Gross hematuria, 442–443
Group A Streptococcus (GAS) pharyngitis, 886–887
Group A β-hemolytic Streptococcus (GAS), 768–769, 886–887, 904–905, 1002
Group B Streptococcus, 636–637, 811
GTPS. See Greater trochanteric pain syndrome
Guarana, 209
Guillain–Barré syndrome (GBS), 420–421
Gum disease. See Gingivitis
Guttate psoriasis, 844
Gynecomastia, 422–423

**H**

HACE. See High-altitude cerebral edema

Haemophilus influenzae infections
- acute bronchitis, 140
- aphthous ulcer, 1030
- cellulitis, 168–173
- conjunctivitis, 214, 215
- croup, 234–235
- epididymitis, 338

- pneumonia, 780
- sinusitis, 928
- tracheitis, 1006
- vulvovaginitis, 1089

Haemophilus influenzae type b (Hib) vaccine, 68, 168, 170, 234, 636, 637

Hair follicle abscess, 378–379

Hairiness, excessive (hirsutism), 476–477, 790–791

Hair loss
- alopecia, 32–33
- telogen effluvium, 32, 970–971
- trichotillomania, 32–33

Hair loss

Hairy leukoplakia, 594–595

Halban theory, of endometriosis, 330

Hallucinations
- delirium and, 252
- hypnagogic, 688–689
- psychosis and, 846–847

Hallucinogens, 954

Hallux valgus (bunion), 144–145, 652–653

Hammer toes, 424–425, 652

HA-MRSA. See Hospital-acquired methicillin-resistant Staphylococcus aureus

Hand dermatitis, acute and recurrent. See Dyshidrosis

Hand-foot-and-mouth disease, 426–427, 1030
Hand–foot syndrome, 48
Hand osteoarthritis, 718–719
Hangman fracture, 177
HAP. See Hospital-acquired pneumonia
HAPE. See High-altitude pulmonary edema
Hard corn (heloma durum), 224–225
Hardening of the arteries. See Vascular dementia
Hashimoto disease (thyroiditis), 514, 530, 990–991
Hashitoxicosis, 514
Hb SS disease. See Sickle cell anemia
HCAP. See Health care associated pneumonia
HCP. See Health care proxy
Headache
  chronic, A-52
  cluster, 428–429
  medication overuse, 430–431
  migraine, 430–431, A-79
  migraine, vertiginous, 574, 1066–1067
  tension, 432–433
Head injury, 128–129. See also Traumatic brain injury
Head lice, 752–753
Health care associated pneumonia (HCAP), 780–781
Health care proxy (HCP), 24–25, 392
Hearing loss, 434–435
  in elderly, 392, 434, 814–815, 998
  eustachian tube dysfunction and, 356–357
  labyrinthitis and, 574–575
  otitis media and, 726–729
  presbycusis and, 814–815, 998
  tinnitus with, 998–999
  vertigo with (Ménière disease), 634–635, 1066–1067
Heart defects
  atrial septal defect, 90–91
  Down syndrome and, 300
  ventricular septal defect, 660, 1064–1065
Heart disease
  menopause and, 644
  rheumatic, 64–65, 660, 662–663, 886–887
Heart failure
  acute decompensated, 436–437
  aortic valvular stenosis and, 64–65
chronic, 438–439
congestive, differential diagnosis of, A-28
cor pulmonale and, 220–221
mitral valve prolapse and, 664–665
Heart murmur, A-53
Heart palpitations, A-84
Heat collapse, 440–441
Heat exhaustion, 440–441
Heat illness, 440–441
Heat injury, 440–441
Heat prostration, 440–441
Heat stroke, 440–441
Heat urticaria, 1042–1043
Heavy menstrual bleeding (HMB), 646–647
Heavy proteinuria, 832–833
Heel pain, 776–777
Heerfordt syndrome. See Sarcoidosis
Helicobacter pylori infection
and functional dyspepsia, 314
and gastritis, 384–385

Human parvovirus B19, 638, 748–749
Hürthle cell carcinoma, 988–989
Hyaline membrane disease. See Neonatal respiratory distress syndrome
Hydrocele, 488–489
Hydrocephalus, normal pressure, 490–491
Hydronephrosis, 492–493
Hydrophobia. See Rabies
Hydrops fetalis, 880–881
Hydrosalpinx, 754–755
Hymenoptera stings/bites, 80–81
Hyperactive delirium, 252
Hyperactivity. See Attention deficit/hyperactivity disorder
Hyperbilirubinemia, A-57
  in Gilbert disease, 396–397
Hypercalcemia, 1040, A-58
Hypercalciuria, 1040, 1041
Hypercholesterolemia, 494–495
Hypercoagulable states, 26, 984–985
Hyperemesis gravidarum, 496–497
Hyperextension injury, cervical, 176–177, A-19–A-20
Hyperglycemia
  in diabetes mellitus type 1, 282–283
  in diabetes mellitus type 2, 284–285
  in diabetic ketoacidosis, 286–287
Hyperhemolytic crisis, 48
Hyperhomocysteinemia, 984
Hyperkalemia, 498–499, A-59
Hyperlipidemia, A-60–A-62
Hypermotility, and diarrhea, 292–293
Hypernatremia, 500–501, A-63
Hyperoxaluria, 1040–1041
Hyperparathyroidism, 191, 502–503
Hyperprolactinemia, 380–381, 504–505, 774–775
Hypersensitivity
  carotid sinus, 158–159, 960–963
  cough reflex, 188
  erythema nodosum, 350–351
  food allergy, 372–373
  Stevens–Johnson syndrome, 240–241, 348
Hypersensitivity pneumonitis, 506–507
Hypersensitivity vasculitis, 240–241, 1060–1061
Hypersomatotropinemia, 774
Hypersplenism, 508–509
Hypertension
  essential, 510–511
  kidney disease in, 190–191
  masked, 510
  in metabolic syndrome, 650–651
  portal, 82–83, 352–353, 800–801
  in pregnancy, 806–807, 810
  resistant, 512–513
  secondary, 510, 512–513
uncontrolled, 512–513
white-coat, 510, 512–513
Hypertension, pulmonary
  arterial, 848–849
  cor pulmonale with, 220–221
  scleroderma and, 910–911
  ventricular septal defect and, 1064
Hyperthermia, 392, 440–441
Hyperthyroidism, 514–515
  chronic diarrhea with, 292–293
  Graves disease, 418–419, 514–515
  subclinical, 514
Hypertonic hyponatremia, 524
Hypertriglyceridemia, 516–517, A-64
Hypertrophic cardiomyopathy, 156–157
Hypertrophic lichen planus, 596
Hyperuricemia, gout, 412–413
Hyperuricosuria, 1040–1041
Hypervolemic hypernatremia, 500–501
Hypervolemic hyponatremia, 524–525
Hypnagogic hallucinations, 688–689
Hypoactive delirium, 252
Hypoalbuminemia, A-65
Hypoandrogenism. See Testosterone deficiency
Hypobaric hypoxia, and in-flight emergency, 26
Hypocalcemia, 1074–1075, A-66
Hypochondriasis, 938–939
Hypochromic anemia. See Iron deficiency anemia
Hypocitraturia, 1040–1041
Hypocomplementemic urticarial vasculitis, 1060–1061
Hypoglycemia, A-67
  diabetic, 518–519
  fasting, 518, 520
  nocturnal, 518, 519
  nondiabetic, 520–521
  reactive, 520–521
Hypogonadism, 38, 978–979
Hypokalemia, 522–523, A-68
Hypomania, 120–121
Hyponatremia, 524–525, A-69
  SIADH and, 524–525, 964–965
tonicity and, 524
Hypoparathyroidism, 526–527
Hypoplastic anemia. See Aplastic anemia
Hyposomatotropinemia, 774
Hypotension, A-70
  orthostatic, 392, 960–963
  syncope with, 960–963
Hypothermia, 376, 392, 528–529
Hypothyroidism, adult, 530–531
Hypotonic hyponatremia, 524
Hypovolemia
  hypernatremia in, 500–501
  hyponatremia in, 524–525
Hypoxia, hypobaric, and in-flight emergency, 26
HZO. See Herpes zoster ophthalmicus

I
Iatrogenic cryptorchidism, 236
IBD. See Inflammatory bowel disease
IBS. See Irritable bowel syndrome
IC/bladder pain syndrome. See Interstitial cystitis
ID. See Intellectual disability
IDA. See Iron deficiency anemia
Idiopathic blenorrhreal arthritis. See Reactive arthritis
Idiopathic dyspepsia. See Functional dyspepsia
Idiopathic hypertension. See Essential hypertension
Idiopathic hypertrophic subaortic stenosis (IHSS). See Hypertrophic cardiomyopathy
Idiopathic interstitial pneumonia (IIP), 294–295
Idiopathic polyneuritis. See Guillain–Barré syndrome
Idiopathic pulmonary arterial hypertension (IPAH), 848–849
Idiopathic pulmonary fibrosis (IPF), 294–295, 852–853
Idiopathic thrombocytopenic purpura, 534–535
Id reaction, 532–533
IgA nephropathy, 404–405, 406
IgA vasculitis (Henoch–Schönlein purpura), 404–405, 406, 450–451, 1060–1061
IHPS. See Infantile hypertrophic pyloric stenosis
IIP. See Idiopathic interstitial pneumonia
ILD. See Interstitial lung disease
Illness anxiety disorder, 938–939
IMB. See Intermenstrual bleeding
IME (in-flight medical emergency), 26–27
Immersion (trench) foot, 376
Immune heparin-induced thrombocytopenia, 452
Immune thrombocytopenia (ITP), 534–535
Immunization. See specific vaccines
Impaction, fecal, 538–539
Impetigo, 536–537
Impotence (erectile dysfunction), 344–345
Inattentiveness. See Attention deficit/hyperactivity disorder
Incarcerated hernia, 462–463
Incisional hernia, 462–463
Inclusion body myositis, 796–797
Incomplete abortion, 1053
Incontinence, fecal, 538–539
    functional nonretentive, 324–325
Incontinence, urinary
    adult female, 540–541
    adult male, 542–543
    benign prostatic hyperplasia and, 824–825
    enuresis, 114–115, 334–335
    geriatric, 392
Indinavir-induced nephritis, 560–561
Induced or therapeutic abortion, 658
Inducible urticaria, 1042
Inevitable abortion, 658
Infantile acne, 10
Infantile colic, 200–201
Infantile hypertrophic pyloric stenosis (IHPS), 856–857
Infantile polyarteritis. See Kawasaki syndrome
Infectious arthritis. See Septic arthritis
Infectious croup. See Croup
Infectious cystitis. See Urinary tract infection
Infectious epididymitis, 338–339
Infectious gastritis, 384–385
Infectious mononucleosis, 544–545
Infectious parotitis. See Mumps
Infective endocarditis, 326–327
Infertility, 546–547, A-71
    chlamydia infection and, 184–185
    endometriosis and, 330–331
    pelvic inflammatory disease and, 546–547, 754–755
    polycystic ovary syndrome and, 546–547, 790–791
Infiltrating ductal carcinoma, 132
Infiltrating lobular carcinoma, 132
Inflammation, medical marijuana for, 630
Inflammatory aneurysm, 50
Inflammatory bowel disease (IBD)
  chronic diarrhea in, 292–293
  colon cancer risk in, 204, 205
  Crohn disease, 204, 205, 232–233, 292–293
  ulcerative colitis, 204, 205, 232–233, 292–293, 1032–1033
Inflammatory breast cancer, 132
Inflammatory myopathy. See Polymyositis/dermatomyositis
Inflammatory prostatitis, asymptomatic, 826
In-flight medical emergency (IME), 26–27
Influenza, 548–549
  antigenic drift and, 548
  meningitis in, 638
  pneumonia in, 548–549
Influenza vaccine, 68, 420, 548, 726
Informed consent, capacity (competence) and, 152–153
Ingrown toenail, 550–551
Inguinal hernia, 462–463
Injury, 552–553
Insemination, intrauterine, 547
Insomnia, 554–555
  in Alzheimer disease, 37
  chronic, 554–555
  and in-flight emergency, 26
  transient/intermittent, 554–555
Institutional abuse, elder, 322–323
Insufficiency fracture, 948–949
Insulin reaction, 518–519
Integrative medicine, 208
Intellectual development disorder, 556–557
Intellectual disability (ID), 556–557
  Down syndrome, 300–301, 556–557
  fetal alcohol syndrome, 556
  fragile X syndrome, 556–557
Intelligence quotient (IQ), 556
Interdigital candidiasis, 150
Interdigital (Morton) neuroma, 652–653, 668–669
Intermediate uveitis, 1048–1049
Intermenstrual bleeding (IMB), 646

Intermetatarsal neuroma. See Interdigital (Morton) neuroma

Internal hemorrhoids, 448–449

International adoption, 22–23

Internet gaming disorder (IGD), 382–383

Internuclear ophthalmoplegia, 674

Interpersonal psychotherapy, 230–231

Interstitial cystitis, 558–559

Interstitial lung disease (ILD), 294–295, 852–853
  scleroderma and, 910–911

Interstitial nephritis, 560–561

Intertrigo. See Candidiasis

Intervertebral disc disorders, 102–103

Intimate partner (domestic) violence, 298–299, 389, 482, 552–553, 584–585, 810

Intracytoplasmic sperm injection, 547

Intraligamentary ectopic pregnancy, 318–319

Intrarenal acute kidney injury, 16–17

Intrauterine device (IUD), 218–219

Intrauterine growth restriction (IUGR), 360

Intrauterine insemination, 547

Invasive SCC, 946

Inverse psoriasis, 844

In vitro fertilization, 547

Iodine-induced hyperthyroidism, 514

Ion channel disorders, 156

IPF. See Idiopathic pulmonary fibrosis

IQ (intelligence quotient), 556

Iridocyclitis, 1048–1049

Iridotrabecular contact (ITC), 400

Iris heterochromia, in Horner syndrome, 486–487

Iritis, 864–865, 1048–1049

Iron deficiency anemia (IDA), 46–47

Iron excess (hemochromatosis), 196–197, 444–445

Irreducible hernia, 462

Irritable bowel syndrome (IBS), 216, 562–563

Irritant dermatitis (ID), 274–275

Ischemic acute tubular necrosis, 16

Ischemic cardiomyopathy, 156–157

Ischemic colitis, 202–203

Ischemic priapism, 820–821

Ischemic stroke, 950–951
Islet cell tumor, in Zollinger–Ellison syndrome, 1094–1095
Isotonic hyponatremia, 524
ITP. See Immune thrombocytopenia
IUD. See Intrauterine device
Ixodes ticks, 608

J
JAE. See Juvenile absence epilepsy
Jaundice, A-57
  breast milk, 135
Jeep disease, 770–771
Jervell and Lange-Nielsen syndrome, 435
Jet lag, 69, 554–555
JIA. See Juvenile idiopathic arthritis
Jock itch, 992–993
Joint disease, degenerative. See Osteoarthritis
Joint pain, chronic, A-23
JPS. See Juvenile polyposis syndrome
Juvenile absence epilepsy (JAE), 914
Juvenile idiopathic arthritis (JIA), 72–73
Juvenile myoclonic epilepsy (JME), 914
Juvenile polyposis syndrome, 206–207
Juvenile recurrent parotitis, 746–747

K
Kanner autism, 98–99
Kaposi sarcoma, 478
Kava, 209
Kawasaki syndrome, 564–565, 1060–1061
Keloidal folliculitis, 370
Keratitis, 214, 222–223
  herpes, 464–465, 468–469
  measles, 625
Keratoacanthoma, 566–567
Keratoconjunctivitis, herpes, 464–465, 468–469
Keratoconjunctivitis sicca, in Sjögren syndrome, 930–931
Keratolysis exfoliativa. See Dyshidrosis
Keratosis
  actinic, 568–569, 946–947
  seborrheic, 570–571
Ketoacidosis, diabetic, 286–287, A-39
Kidney disease
acute glomerulonephritis, 404–405
acute tubular necrosis, 16
chronic, 190–191
IgA nephropathy, 404–405
infection (pyelonephritis), 854–855
interstitial nephritis, 560–561
lupus nephritis, 404–405, 406, 606–607
nephrotic syndrome, 692–693
polycystic, 788–789
postinfectious glomerulonephritis, 404–407, 536, 537
renal tubular acidosis, 866–867
Kidney failure, acute (acute kidney injury), 16–17, 560
Kidney malignancy, Wilms tumor, 1092–1093
Kidney stones (renal calculi)
  with Crohn disease, 232
  hematuria with, 442–443
  hydronephrosis with, 492–493
Knee injury, meniscal, 642–643
Knee osteoarthritis, 572–573, 718–719
Knee pain, 572–573, A-72
Knee sprain, 944
Korsakoff syndrome, 1076–1077
Kyleena, 219

L
Labor
  bloody show of, 1052
  preterm, 818–819, 1053
Labyrinthitis, 574–575, 1066–1067
Lactate dehydrogenase elevation, A-73
Lactation, 134–135. See also Breastfeeding
Lactation, disordered. See Galactorrhea
Lactational amenorrhea method, 219
Lactose intolerance, 292–293, 576–577
Lamellar dyshidrosis, 308–309
Landry ascending paralysis. See Guillain–Barré syndrome
Landry–Guillain–Barré–Strohl syndrome. See Guillain–Barré syndrome
LARCs. See Long-acting reversible contraceptives
Large cell lung cancer, 602–603
Large-vessel vasculitis, 1060–1061
Laryngitis, 578–579
Laryngopharyngeal reflux disease (LPRD), 578–579
Laryngotracheitis. See Laryngitis
Laryngotracheobronchitis (croup), 234–235, 578–579, 625, 1006–1007
Latent syphilis, 966–967
Latent tuberculosis (LTBI), 1022, 1024–1025
Lateral ankle sprains, 942–943
Lateral epicondylitis, 336–337
Laxative abuse, 142–143
LBP. See Low back pain
Lead poisoning/toxicity, 580–581
   nephritis in, 560–561
Left ventricular noncompaction (LVNC), 156
Legionella pneumophila, 582
Legionnaires’ disease, 582–583, 780
Leg ulcers, venous insufficiency, 1062–1063
Leiomyomas, uterine, 1046–1047
Leiomyosarcoma, 328, 1054, 1082
Lentigo maligna, 632
Leptocytosis, hereditary. See Thalassemia
Lesbian, gay, bisexual, or transgender (LGBT) health
   gay, 388–389
   lesbian, 584–585
   transgender, 1008–1009
Lesbian health, 584–585
Leukemia
   acute lymphoblastic, in adults, 586–587
   acute myeloid, 588–589, 684–685
   chronic lymphocytic, 590–591
   chronic myelogenous, 592–593, 686–687
   plasma cell (See Multiple myeloma)
Leukocytosis, A-51
Leukoderma. See Vitiligo
Leukoplakia, oral, 594–595
Levonorgestrel emergency contraception, 219
Levonorgestrel intrauterine system, 218–219
Lewy body dementia, 254–255
LGBT health
   gay, 388–389
   lesbian, 584–585
   transgender, 1008–1009
LGMD. See Limb-girdle muscular dystrophy
Lice (pediculosis), 80–81, 752–753
Lichenoid eruptions, 240–241, 596–597
Lichen planopilaris, 596
Lichen planus (LP), 596–597, 1056–1057
Lichen planus pemphigoides, 596
Lichen sclerosus
  penile, 106–107
  vaginal, 1056–1057
Lichen simplex chronicus, 598–599
Licorice, 209
Li–Fraumeni syndrome, 132
Light-sensitive seborrhea. See Perioral dermatitis
Liletta, 219
Lily of the valley, 209
Limb-girdle muscular dystrophy (LGMD), 678–679
Linear lichen planus, 596
Lipid disorders
  granuloma annulare in, 414
  hypercholesterolemia, 494–495
  hyperlipidemia, A-60–A-62
  hypertriglyceridemia, 516–517, A-64
  metabolic syndrome, 650–651
Listeria monocytogenes, 374–375, 636–637
Lithium-induced nephritis, 560–561
Liver cancer (HCC), 458–459
Liver coma. See Hepatic encephalopathy
Liver disease. See also Cirrhosis
  acetaminophen poisoning and, 6–7
  ascites with, 82–83
  encephalopathy in, 196, 197, 454–455, 800–801
  esophageal varices with, 352–353
  nonalcoholic fatty, 702–703
Liver enlargement (hepatomegaly), A-56
Living will (LW), 24–25, 392
Lobular capillary hemangioma, 416–417
Localized neurodermatitis. See Lichen simplex chronicus
Löfgren syndrome. See Sarcoidosis
Long-acting reversible contraceptives (LARCs), 218–219
Long QT interval, 156, 600–601
Lo Ovral, 219
Louse-borne typhus. See Typhus fevers
Low back pain, 102–103
    chronic, A-74
Lower abdominal pain, A-3
Lower extremity (leg) ulcer, venous insufficiency, 1062–1063
Low-risk pulmonary embolism, 850
Low T. See Testosterone deficiency
LP. See Lichen planus
LPRD. See Laryngopharyngeal reflux disease
LSC. See Lichen simplex chronicus
LTBI. See Latent tuberculosis
Lumbago. See Low back pain
Lumbar (intervertebral) disc disorders, 102–103
Lumbar sprain/strain, 102–103
Lumbar stenosis, 940–941
Lung cancer
    non-small cell, 602–603
    primary malignancies, 602–603
    small cell, 602–603
Lung disease
    in-flight emergency, 26–27
Lupus erythematosus, systemic. See Systemic lupus erythematosus
Lupus-like perioral dermatitis. See Perioral dermatitis
Lupus mastitis, 620
Lupus nephritis, 404–405, 406, 560, 561, 606–607
Lupus nephropathy, 692
Lupus vasculitis, 1060–1061
L.W. See Living will
Lyell syndrome. See Toxic epidermal necrolysis
Lyme disease, 78–79, 608–609
Lymphadenopathy, A-75
Lymphangiosarcoma, 613
Lymphangitis, 610–611
Lymphedema, 612–613
Lymphoblastic leukemia, acute, in adults, 586–587
Lymphocytic choriomeningitis virus (LCMV), 638
Lymphocytic leukemia, chronic, 590–591
Lymphocytopenia, A-76
Lymphoma, Hodgkin, 480–481
Lymphopenia, A-76
Lynch syndrome, 204, 206, 730

M
MAC. See Mycobacterium avium complex
MacArthur Competence Assessment Tool-Treatment (MacCAT-T), 152
Macroadenoma, 774–775
Macroprolactinemia, 504
Macular degeneration, age-related, 614–615
Magnetic bracelets, 209
Magnetic resonance imaging, breast, 304
MAHA. See Microangiopathic hemolytic anemia
Maisonneuve fracture, 54
Major depressive disorder (MDD), 260–261
  adolescent, 262–263
  postpartum, 266–267
  treatment-resistant, 263, 268–269
Major depressive episode, A-38
Malaise, postexertional, 680
Malaria, 616–617
Malaria prophylaxis, for travel, 68
Malassezia folliculitis, 370
Male breast hypertrophy (gynecomastia), 422–423
Male infertility, 546–547
Male pattern hair loss, 32
Male sexual dysfunction. See Sexual dysfunction in men
Mallet toe, 424–425
Maltreatment, child. See Child abuse
Mammary abscess. See Breast abscess
Mammary dysplasia. See Fibrocystic changes of breast
Mammography, 132–133, 304–305
Mania
  in bipolar I disorder, 118–119
  in bipolar II disorder, 120–121
Manipulative and body-based therapies, 208
March (stress) fracture, 948–949
Marie-Strümpell disease (ankylosing spondylitis), 56–57
Marijuana
  marijuana use disorder, 618–619, 954–955
  medical marijuana, 630–631
Marjolin ulcer, 946
Marker X syndrome. See Fragile X syndrome
Martin–Bell syndrome. See Fragile X syndrome
Masked hypertension, 510
Massage, carotid sinus, 158–159
Massage therapy, 208
Massive pulmonary embolism, 850
Mastalgia, 366
Mastectomy, 132–133
  for ductal carcinoma in situ, 305
  lymphedema after, 612–613
Mastitis, 130–131, 620–621
  breastfeeding and, 135, 620–621
  chronic cystic (See Fibrocystic changes of breast)
Mastodynia. See Mastalgia
Mastoiditis, 622–623
McCune–Albright syndrome, 238, 774
MCD. See Minimal change disease
MCI. See Mild cognitive impairment
MDD. See Major depressive disorder
MDR tuberculosis. See Multidrug-resistant (MDR) tuberculosis
MDSs. See Myelodysplastic syndromes
Mealtime syndrome, 896
Measles (rubeola), 624–625
Measles, German, 626–627
Measles croup, 625
Measles-mumps-rubella vaccine (MMR), 68, 624–627, 676, 746
Measles-mumps-rubella-varicella vaccine (MMRV), 180, 624, 626–627
Measles vaccine, 624–625
Medial ankle sprains, 942–943
Medial epicondylitis, 336–337
Medial tibial stress syndrome (MTSS), 628–629
Median nerve compression (carpal tunnel syndrome), 162–163
Medical care-associated pneumonia, 780–781
Medical directives, 24–25
Medical marijuana, 630–631
Medical orders for life-sustaining treatment (MOLST), 24–25, 392
Medication-induced psychosis, 846
Medication overuse headache, 430–431
Meditation, 208–209
Mediterranean anemia. See Thalassemia
Medium-vessel vasculitis, 1060–1061
Medroxyprogesterone (Depo-Provera), 218
Medullary thyroid carcinoma (MTC), 988–989
Megacolon, congenital (Hirschsprung disease), 216
Meibomian stye. See Hordeolum
Meige disease, 612
Melanoma, 632–633
atypical mole (dysplastic nevus) syndrome and, 96–97, 632–633
vaginal, 1054
vulvar, 1082
Melatonin, for sleep disorders, 115, 555, 935
Membranoproliferative glomerulonephritis (MGN), 404–405, 406, 692
Membranous nephropathy, 692
Ménière disease, 634–635, 1066–1067
Ménière syndrome, 634
Meningitis, 636–641
aseptic, 638
bacterial, 636–637
gonococcal, 410–411
herpes, 466, 468, 638
mumps, 676–677
viral, 638–639
Meningococcal conjunctivitis, 214–215
Meningococcal disease, 636–637, 640–641
Meningococcal vaccine, 68, 637, 640
Meningococcemia, 640
Meniscal injury, 642–643
Menopausal transition (MT), 644
Menopause, 644–645
definition of, 644
evaluation and management of, A-77–A-78
genitourinary syndrome of, 1086–1087
osteoporosis in, 644–645, 722–723, A-77
Menorrhagia, 646–647
Menstrual cramps. See Dysmenorrhea
Menstrual-related migraine, 430
Menstruation
abnormal (dysfunctional) bleeding in, 2–3, 646–647
absence of (See Amenorrhea)
cessation of (See Menopause)
cyclic vomiting syndrome with, 242
female athlete triad and, 362–363
heavy bleeding in (menorrhagia), 646–647
painful (dysmenorrhea), 310–311, 330–331
polycystic ovary syndrome and, 790–791
premenstrual disorders with, 262, 808–809
Mental retardation, insensitivity of term, 556, 557
Mental status, altered
carbon monoxide poisoning, 154
delirium, 252–253, 392, A-36
hepatic encephalopathy, 196–197, 800–801
in-flight emergency, 26–27
serotonin syndrome, 922
Men who have sex with men (MSM), 388–389
Mesothelioma, 602, 648–649
Metabolic syndrome, 516, 650–651
in polycystic ovary syndrome, 790–791
Metatarsalgia, 652–653
definition of, 652
Morton, 652–653, 668–669
Methicillin-resistant Staphylococcus aureus (MRSA)
breast infection, 130–131, 620–621
cellulitis, 168–173
folliculitis, 370–371
furunculosis, 378–379
impetigo, 536–537
infective endocarditis, 326
mastoiditis, 622–623
otitis externa, 724
paronychia, 744–745
pneumonia, 780
pyelonephritis, 855
sinusitis, 928
skin infections, 654–655
tracheitis, 1006
Metritis. See Endometritis
Metrorrhagia, 646
MGN. See Membranoproliferative glomerulonephritis
MI. See Myocardial infarction
Microadenoma, 774–775
Microangiopathic hemolytic anemia (MAHA), 986–987
Microcytic anemia. See Iron deficiency anemia
Micronor, 218
Microscopic hematuria, 442–443
Microscopic polyangiitis (MPA), 404, 1060–1061
Middle ear infection. See Otitis media
Migraine, 430–431
  with aura, 430
  without aura, 430
  treatment, A-79
  vestibular/vertiginous, 574, 1066–1067
Mild cognitive impairment (MCI), 36, 656–657
Mild periodontal disease. See Gingivitis
Mild traumatic brain injury (MTBI)
  concussion, 128–129
  postconcussion syndrome, 128–129, 802–803
  sideline evaluation, A-27
Military sexual trauma (MST), 860
Milk allergy, 372–373
Miller Fisher syndrome (MFS), 420
Milroy disease, 612–613
Mind–body medicine, 208, 209
Minimal change disease (MCD), 692–693
Ministroke. See Transient ischemic attack
Miosis, in Horner syndrome, 486–487
Mirena, 218–219
Miscarriage, 658–659, 1052–1053
Miscarriage, recurrent, 658–659
Missed abortion, 658
Mitchell causalgia. See Complex regional pain syndrome
Mitral regurgitation, 660–661
Mitral stenosis (MS), 662–663
Mitral valve prolapse (MVP), 664–665
Mixed delirium, 252
Mixed hearing loss, 434–435
Mixed incontinence, 540–543
Mixed müllerian sarcoma, 328
MMD. See Myotonic muscular dystrophy
Mole, atypical, 96–97, 632–633
Mollaret syndrome, 466, 638
Molluscum contagiosum, 666–667
Mondor disease, 958
Monilia. See Candidiasis
Monkey bites, 122–123
Monoclonal gammopathy of undetermined significance (MGUS), 672
Mononucleosis, infectious, 544–545
Mood disorders. See specific types
Moraxella catarrhalis, 140, 726, 728, 928, 1006
Morbilliform drug reactions, 240–241
Morbus Dupuytren. See Dupuytren contracture
Morning sickness, 496–497
Morton neuroma, 652–653, 668–669
Motion sickness, 69, 670–671
Motivational interviewing, 230–231
Motor vehicle accidents, 552–553
Mountain (altitude) sickness, 34–35, 69
MPA. See Microscopic polyangiitis
MPNs. See Myeloproliferative neoplasms
MRSA. See Methicillin-resistant Staphylococcus aureus
MS. See Mitral stenosis; Multiple sclerosis
MSM. See Men who have sex with men
MST. See Military sexual trauma
MTBI. See Mild traumatic brain injury
MTC. See Medullary thyroid carcinoma
MTSS. See Medial tibial stress syndrome
Mucocutaneous candidiasis, 150–151
Mucocutaneous lymph node syndrome (MLNS). See Kawasaki syndrome
Mucoid otitis media. See Otitis media
Mucosal papillomas, 1090
Mucus plug, in labor, 1052
Muir–Torre syndrome, 566–567
Multidrug-resistant (MDR) tuberculosis, 1023
Multi-infarct dementia. See Vascular dementia
Multiple endocrine neoplasia syndromes
  Cushing disease/syndrome with, 238
  hyperparathyroidism in, 502
  MEN1, 1094–1095
  thyroid cancer with, 988, 989
Multiple myeloma, 672–673
Multiple sclerosis (MS), 674–675
  clinically isolated syndrome, 674
  medical marijuana for, 630
  optic neuritis in, 674–675, 714–715
  primary progressive, 674
  relapsing-remitting, 674
  secondary progressive, 674
Mumps, 676–677, 746–747
Mumps meningitis, 638
Murine (endemic) typhus, 1028–1029
Muscle contraction headache. See Tension headache
Muscular dystrophy, 678–679
Muscular subaortic stenosis. See Hypertrophic cardiomyopathy
MUTYH-associated polyposis syndromes, 206
MVP. See Mitral valve prolapse
Myalgic encephalomyelitis, 680–681
Myasthenia gravis, 682–683
Mycobacterium avium complex (MAC), 478–479
Mycobacterium tuberculosis, 140, 720, 1022, 1024
Mycoplasma pneumoniae, 234, 782–783
Myelodysplastic syndromes (MDSs), 588–589, 684–685
Myelofibrosis, primary, 686–687
Myeloid/myelogenous leukemia
   acute, 588–589, 684–685
   chronic, 592–593, 686–687
Myeloma, multiple, 672–673
Myeloproliferative neoplasm (MPN), 588
Myeloproliferative neoplasms (MPNs), 686–687
Myocardial infarction (MI)
   acute, 14
   non-ST-segment elevation (NSTEMI), 12–13, 226–227
   ST-segment elevation (STEMI), 14–15, 226–227
   ventricular septal defect in, 1064–1065
Myocarditis, 156
Myoclonic absence seizure, 914–915
Myoclonus, sleep or nocturnal. See Periodic limb movement disorder
Myofascial pain–dysfunction syndrome. See Temporomandibular joint disorder
Myofibroma. See Myomas, uterine
Myomas, uterine, 1046–1047
Myometritis. See Endometritis
Myopericarditis, 758–759
Myositis. See Polymyositis/dermatomyositis
Myotonic muscular dystrophy (MMD), 678–679
Myxedema. See Hypothyroidism
Myxomatous mitral valve. See Mitral valve prolapse

N
Nail(s)
abnormalities, A-80
fungal infection (onychomycosis), 712–713
inflammation (paronychia), 744–745
ingrown toenail, 550–551
psoriatic disease, 844
Nail lichen planus, 596
Napkin dermatitis. See Diaper dermatitis
Nappy rash. See Diaper dermatitis
Narcolepsy, 688–689
Nasal polyps, 690–691
NASH. See Nonalcoholic steatohepatitis
Natural menopause, 644
Naturopathy, 208
Nausea
  chemotherapy-induced, medical marijuana for, 630
  in hyperemesis gravidarum, 496–497
  in motion sickness, 670–671
Neck injuries, cervical hyperextension, 176–177, A-19–A-20
Necrotizing arteritis. See Polyarteritis nodosa
Necrotizing autoimmune myositis, 796–797
Necrotizing cellulitis, 168–169
Necrotizing fasciitis, 654–655
Necrotizing malignant otitis externa, 724–725
Necrotizing ulcerative gingivitis, acute, 398–399, 1070–1071
Negative symptoms, in psychosis, 846
Neglect
  child, 182–183
  self-, elder, 322–323
Neisseria gonorrhoeae, 410. See also specific gonococcal infections
Neisseria meningitidis, 636–637, 640
Neonatal acne, 10
Neonatal parotitis, 746–747
Neonatal respiratory distress syndrome (NRDS), 870–871
Nephritis
  interstitial, 560–561
  lupus, 404–405, 406, 560, 561, 606–607
Nephroblastoma. See Wilms tumor
Nephrolithiasis
  hematuria with, 442–443
  hydroureter with, 492–493
Nephropathy
diabetic, 692
IgA, 404–405, 406
lupus, 692
urate, 561
Nephrotic-range proteinuria, 832–833
Nephrotic syndrome, 692–693
Nervous fever. See Typhoid fever
Neuralgia
  postherpetic, 468–469
  posttraumatic (See Complex regional pain syndrome)
  trigeminal, 962, 1016–1017
Neurocardiogenic syncope, 960–963
Neurodermatitis, 598–599
Neurodermatitis circumscrippta. See Lichen simplex chronicus
Neuroendocrine tumor, chronic diarrhea with, 292–293
Neurofibromatosis type 1, 694–695
Neurofibromatosis type 2, 694
Neuroleptic malignant syndrome, 846–847
Neuroma, Morton (interdigital), 652–653, 668–669
Neuromuscular dysphagia, 316
Neuropathic pain, 194, 696–697
Neuropathy
  diabetic, 288–289, 698–699
  facial nerve (Bell palsy), 116–117
  Guillain–Barré syndrome, 420–421
  median nerve (carpal tunnel syndrome), 162–163
  peripheral, 698–699
  posterior tibial nerve (tarsal tunnel syndrome), 968–969
Neurosyphilis, 966–967
Neutropenia, A-81
Neutropenia, in myelodysplastic syndromes, 684–685
Nevus
  abnormal, 96–97, 632–633
  dysplastic, 96–97, 632–633
  giant congenital, 632
Nexplanon, 219
NFLD. See Nonalcoholic fatty liver disease
Nicotine addiction, 388, 584, 700–701, 954–955, 1000–1001
Nightmares, in children, 114
Night terrors, in children, 114
Night waking, in children, 114
NSAIDs. See Nonsteroidal anti-inflammatory drugs
NSCLC. See Non-small cell lung cancer
NSTEMI (non-ST-segment elevation myocardial infarction), 12–13, 226–227
Nut allergy, 372–373
NuvaRing, 218
Nystagmus, labyrinthitis and, 574–575

O
OA. See Osteoarthritis
Obesity, 706–707
and diabetes mellitus type 2, 284
and hypertension, 512–513
and metabolic syndrome, 650–651
and obstructive sleep apnea, 932–933
and polycystic ovary syndrome, 790–791
surgery for (See Bariatric surgery)
and vitamin D deficiency, 1075, 1077
Objective tinnitus, 998–999
Obsessive-compulsive disorder (OCD), 708–709, 1002–1003
Obstetric emergency, in-flight, 26–27
Obstipation. See Constipation
Obstructive atelectasis, 86–87
Obstructive sleep apnea (OSA), 932–933
pediatric, 114–115
Obstructive uropathy, 492
Occupational allergic rhinitis, 888
OCD. See Obsessive-compulsive disorder
Ocular chemical burns, 710–711
Ocular myasthenia gravis, 682–683
Ocular rosacea, 8
Ocular toxoplasmosis, 1004–1005
Oculopharyngeal muscular dystrophy (OPMD), 678–679
Oculosympathetic deficiency. See Horner syndrome
Oculosympathetic paralysis. See Horner syndrome
Oculosympathetic paresis. See Horner syndrome
Oculosympathetic syndrome. See Horner syndrome
Odontoid fractures, 177
Ogestrel, 219
OME. See Otitis media with effusion
Omega-3 fatty acids, 209
Onychocryptosis. See Ingrown toenail
Onychomycosis, 712–713
Open-angle glaucoma, primary, 402–403
Ophthalmia neonatorum, 214, 410–411
Opioid abuse, 302–303, 954–955
Opioid detoxification, 303
OPMD. See Oculopharyngeal muscular dystrophy
Optic neuritis, 464–465, 674–675, 714–715
Oral contraceptives, 218–219
Oral leukoplakia, 594–595
Oral rehydration (ORT), 250–251
Orbital cellulitis, 168, 170–171, 172
Orchidopexy (orchiopexy), 237
Orchitis
epididymo-orchitis, 338
Henoch-Schönlein purpura and, 450, 451
mumps, 676–677
Organic brain syndrome. See Delirium
Orgasm
female, disorders in, 924–925
male, disorders in (ejaculatory disorders), 320–321
Orofacial pain. See Temporomandibular joint disorder
Oropharyngeal candidiasis, 150–151
Oropharyngeal dysphagia, 316–317
ORT. See Oral rehydration
Ortho Evra, 218
Orthostatic hypotension, 392, 960–963
Orthostatic intolerance, 680
OSA. See Obstructive sleep apnea
Osgood–Schlatter disease (OSD), 716–717
Osler phenomenon, 512
Osmotic diarrhea, 292–293
Osteoarthritis (OA), 718–719
Osteoarthritis of knee, 572–573, 718–719
Osteoarthritis of shoulder, 926–927
Osteoarthritis. See Osteoarthritis
Osteomyelitis, 654, 720–721
Osteopathic manipulation, 208
Osteopenia, 722–723
in menopause, 644, A-77
Osteoporosis, 722–723
in female athlete triad, 362–363
in menopause, 644–645, 722–723, A-77
Ostium primum defect, 90
Ostium secundum defect, 90
Otitis externa, 724–725
Otitis media, 726–729
    acute, 726–727
    chronic, 726–727
    mastoiditis with, 622–623
    measles and, 625
Otitis media with effusion (OME), 728–729
Otosclerosis, 434
Ovarian cancer, 584, 730–731
Ovarian cyst, ruptured, 732–733
Ovarian ectopic pregnancy, 318–319
Ovarian insufficiency, primary, 644
Ovarian reserve, diminished, 546
Overflow diarrhea, 538–539
Overflow incontinence, 540–543
Overflow proteinuria, 832–833
Overweight, 706–707. See also Obesity

P
pACP. See Pediatric advance care directive
PAD. See Peripheral arterial disease
Paget disease of breast, 132
PAH. See Pulmonary arterial hypertension
Pain

shoulder, 20–21, 894–895, 926–927, A-103
temporomandibular joint, 972–973
zoster-associated, 470–471
Pain syndrome
  bladder (See Interstitial cystitis)
  chronic pelvic (chronic prostatitis), 826
  complex regional, 210–211
  greater trochanteric, 1020–1021
  patellofemoral, 572–573, 750–751
Palliative care, 734–735
Palmar fibromatosis, 306–307
Palmar pompholyx reaction. See Dyshidrosis
Palmoplantar warts, 1090
Palpable breast mass, A-83
Palpable cryptorchidism, 236
Palpitations, A-84
PAN. See Polyarteritis nodosa
Panarteritis. See Polyarteritis nodosa
Pancreatic cancer, 736–737
Pancreatic ulcerogenic tumor syndrome. See Zollinger–Ellison syndrome
Pancreatitis
  acute, 738–739
  hypertriglyceridemia and, 516–517
PANDAS, 1002
Pandysautonomia, acute, 420
Panic attack, 740–741
Panic disorder, 740–741
Panmyelophthisis. See Aplastic anemia
Pantaloon hernia, 462–463
Panuveitis, 1048–1049
Papillary serous carcinoma, endometrial, 328
Papillary thyroid carcinoma, 988–989
Papillitis. See Optic neuritis
Papillomas, mucosal, 1090
Papillomavirus. See Human papillomavirus
Pap smear
  abnormal, 4–5
  in abnormal uterine bleeding, 2
  in cervical malignancy, 4–5, 178–179
  in nonpregnant women 25 years or older, normal and abnormal, A-85
  in pregnant women, 810–811
  in women ages 21–24 years, normal and abnormal, A-86
Papulopustular facial dermatitis. See Perioral dermatitis
Papulopustular rosacea (PPR), 8
Paracetamol poisoning. See Acetaminophen poisoning
ParaGard, 218–219
ParaInfluenza, 234
Paralysis
  facial, 116–117
  Landry ascending (See Guillain–Barré syndrome)
  oculosympathetic (See Horner syndrome)
  sleep, 688–689
Paraphimosis, 106–107
Parasitic infections. See also specific types
  folliculitis, 370–371
  lice (pediculosis), 80–81, 752–753
  pinworms, 772–773, 1088–1089
scabies, 80–81, 902–903
trichomoniasis, 1014–1015
Parasternal chondrodynia. See Costochondritis
Parathyroid hormone (PTH)
  chronic kidney disease and, 191
deficiency, 526–527
elevated serum, 191, 502–503
Paratrigeminal syndromes, 486
Parechovirus 3, 638
Parenthood, lesbians and, 584
Parkinson disease (PD), 152, 354–355, 742–743, A-87
Parkinsonism, 846–847
Paronychia, 150, 744–745
Parotid calculi, 746, 896–897
Parotitis
  acute and chronic, 746–747
epidemic and infectious (mumps), 676–677
Pars planitis, 1048–1049
Partial (focal) seizures, 916–917
Parvovirus B19 infection, 638, 748–749
Passive atelectasis, 86–87
Patch, contraceptive, 218
Patellar tendinopathy, 572–573
Patellofemoral pain syndrome, 572–573, 750–751
Pattern hair loss, 32
Patulous eustachian tube dysfunction, 356
Pauci-immune crescentic glomerulonephritis, 406
Pauci-immune glomerulonephritis, 404
PCOS. See Polycystic ovary syndrome
PCS. See Postconcussion syndrome
PD. See Parkinson disease
PDS. See Postprandial distress syndrome
PE. See Pulmonary embolism
Peanut allergy, 372–373
Pedestrian injuries, 552–553
Pediatric advance care directive (pACP), 24
Pediatric autoimmune neuropsychiatric disorders associated with streptococcal infections (PANDAS), 1002
Pediatric exanthems, A-88
Pediculosis, 80–81, 752–753
Pediculus humanus, 752
Pedunculated seborrheic keratosis, 570
Pelvic inflammatory disease (PID), 754–755
  chlamydial, 184–185, 754–755
  gonococcal, 410–411, 754–755
  infertility in, 546–547, 754–755
  IUDs and, 219
Pelvic organ prolapse, 1044–1045
Pelvic (pelvic girdle) pain, A-89
Pendred syndrome, 434–435
Penis
  erectile dysfunction, 344–345
  foreskin constriction (paraphimosis), 106–107
  foreskin tightness (phimosis), 106–107
  lichen sclerosus of, 106–107
  prolonged erection (priapism), 820–821
  sclerosing lymphangitis of, 610
PEP. See Postexposure prophylaxis
Peptic stricture, 386–387
Peptic ulcer disease, 756–757
Perennial allergic rhinitis, 888
Perianal cellulitis, 168
Perianal fistula, 40
Periarteritis. See Polyarteritis nodosa
Pericapsulitis. See Adhesive capsulitis
Pericarditis, 758–759
Perifolliculitis, 370
Perimenopause, 644
Perimyocarditis, 758–759
Perimyositis. See Medial tibial stress syndrome
Periodic limb movement disorder, 760–761
Periodontal disease, mild. See Gingivitis
Perionychia. See Paronychia
Perioral dermatitis, 370
Periorbital cellulitis, 168, 172–173
Periorificial dermatitis. See Perioral dermatitis
Periostitis. See Medial tibial stress syndrome
Peripartum cardiomyopathy (PPCM), 156
Peripheral arterial disease (PAD), 762–763
Peripheral breast abscess. See Breast abscess
Peripheral neurofibromatosis. See Neurofibromatosis type 1
Peripheral neuropathy, 698–699
Peripheral uveitis, 1048–1049
Perirectal abscess, 40
Peritonitis, acute, 764–765
Peritonsillar cellulitis, 168
Perlèche (angular cheilitis), 150
Pernicious anemia, 1072–1073, 1076–1077
Pernio (chilblains), 376
Persistent depressive disorder, 262
Persistent pulmonary hypertension of the newborn (PPHN), 848
Personality disorders, 126–127, 231, 846
Pertussis, 766–767
Pervasive developmental disorder not otherwise specified (PDD-NOS), 98–99
Pes anserine bursitis (pes anserine syndrome), 148–149, 572
Petit mal seizures. See Absence seizures
Peutz–Jeghers syndrome, 132, 204, 206
Peyronie disease, 306, 344
Phakomatoses, 694–695
Pharyngeal-cervical-brachial GBS, 420
Pharyngitis, 768–769, 904–905
  acute bronchitis and, 140–141
  gonococcal, 410–411
Phimosis, 106–107
Phlebitis. See Superficial thrombophlebitis
Phlebothrombosis. See Superficial thrombophlebitis
Phosphate stones, 1040–1041
Photosensitivity drug reactions, 240–241
Phyllodes tumor, 132
Phymatous rosacea, 8
Physical abuse (child abuse), 182–183, A-22
Physician order for life-sustaining treatment (POLST), 24–25, 392
Physiologic vertigo. See Motion sickness
Pickwickian syndrome. See Obstructive sleep apnea
PID. See Pelvic inflammatory disease
Pig bites, 122–123
Pili incarnate. See Pseudofolliculitis barbae
Pilon fracture, 54
Pilonidal disease, 770–771
Pingueculitis, 214
Pink eye. See Conjunctivitis
Pinworms, 772–773, 1088–1089
Pituitary adenoma, 238, 380–381, 504–505, 774–775
Pityriasis versicolor. See Tinea versicolor
Pityrosporum folliculitis, 370
Placebo effects, 231
Placenta accreta, 1052
Placenta increta, 1052
Placental abruption, 1052–1053
Placenta percreta, 1052
Placenta previa, 1052–1053
Planar warts, 1090
Plan B, 219
Plan B One-Step, 219
Plantar digital neuritis. See Morton neuroma
Plantar fasciitis, 776–777
Plantar warts, 1090–1091
Plaque psoriasis (vulgaris), 844
Plasma cell leukemia. See Multiple myeloma
Plasma cell myeloma. See Multiple myeloma
Plasmodium falciparum, 616–617
Plasmodium knowlesi, 616
Plasmodium malariae, 616–617
Plasmodium ovale, 616–617
Plasmodium vivax, 616–617
Plateau iris syndrome, 400–401
Pleomorphic rhabdomyosarcoma, 884
Pleural effusion, 778–779
Plummer disease, 514
PMF. See Primary myelofibrosis
PMNE. See Primary monosymptomatic nocturnal enuresis
PMR. See Polymyalgia rheumatica
PMS. See Premenstrual syndrome
PNES. See Psychogenic nonepileptic seizures
Pneumococcal vaccine, 68, 636, 726, 780, 929
Pneumocystis jiroveci, 478–479, 784–785
Pneumonia
  bacterial, 780–781
  community-acquired, 780–781
  herpes, 468–469
  HIV-related, 478–479, 784–785
  hospital-acquired (nosocomial), 780–781
  influenza, 548–549
  interstitial, 294–295
Legionnaires’ disease, 582–583, 780
measles, 624–625
mycoplasma, 782–783
Pneumocystis jiroveci, 478–479, 784–785
RSV, 872
usual interstitial, 852–853
ventilator-associated, 780–781
Pneumonitis, hypersensitivity, 506–507
Pneumothorax, in-flight emergency, 26–27
Poison exposure and treatment, A-90–A-91
Poisonings (toxicity), 552–553
acetaminophen, 6–7, A-5
bacterial food, 374–375, 898–899
carbon monoxide, 154–155
lead, 560–561, 580–581
salicylate, A-101
serotonin syndrome, 261, 922–923
vitamin, 1076, 1077
Poke root, 209
Polio vaccine, 68
POLST/MOLST forms, 24–25, 392
Polyarteritis nodosa (PAN), 786–787, 1060–1061
Polycystic kidney disease, 788–789
Polycystic ovary syndrome (PCOS), 790–791
amenorrhea in, 38, 790–791
hirsutism in, 476–477, 790–791
infertility in, 546–547, 790–791
Polycythemia vera (PV), 686–687, 792–793
Polymenorrhea, 646
Polymyalgia rheumatica (PMR), 794–795
Polymyositis/dermatomyositis, 796–797
Polyneuritis cranialis, 420
Polyneuropathy, diabetic, 288–289
Polypharmacy, 392–393
Polyps
  colonic, 206–207
  nasal, 690–691
Polyuria, 542
Pompholyx, 308–309
Poorly differentiated thyroid carcinoma (PDTC), 988–989
Popliteal (Baker) cyst, 798–799
Portal hypertension, 82–83, 352–353, 800–801
Portosystemic encephalopathy. See Hepatic encephalopathy
Positive symptoms, in psychosis, 846
Postconcussion syndrome (PCS), 128–129, 802–803
Posterior tibial nerve compression, 968–969
Posterior uveitis, 1048–1049
Posterior vitreous detachment, 876
Postexertional malaise, 680
Postexposure prophylaxis (PEP), in HIV, 388–389, 478
Postherpetic neuralgia (PHN), 468–469
Posthitis, 106–107
Postinfectious glomerulonephritis, 404–407, 536, 537
Post-Lyme disease syndrome, 608–609
Postmenopause, definition of, 644
Postnasal drip syndrome, 188–189
Postpartum “blues,” 266
Postpartum depression, 266–267
Postpartum infections, 332–333
Postpartum psychosis, 266, 267
Postpartum thyroiditis, 266, 514, 990–991
Postprandial distress syndrome (PDS), 314–315
Postprandial dyspepsia. See Functional dyspepsia
Postprandial hypoglycemia, 520–521
Postrenal acute kidney injury, 16–17
Postseptal (orbital) cellulitis, 168, 170–171, 172
Poststreptococcal glomerulonephritis, 404, 406–407, 536, 537
Poststroke dementia. See Vascular dementia
Postterm pregnancy, 811
Postthrombotic syndrome (PTS), 249
Posttraumatic neuralgia. See Complex regional pain syndrome
Posttraumatic osteomyelitis, 720–721
Postural (orthostatic) hypotension, 392, 960–963
Postviral fatigue syndrome, 680–681
Potassium
   hyperkalemia, 498–499, A-59
   hypokalemia, 522–523, A-68
Power of attorney, durable, 24–25, 392
Preadolescent acne, 10
Preclinical Alzheimer disease, 36
Precocious puberty, A-92
Prediabetes, 408–409
Preeclampsia, 806–807, 810
Preexposure prophylaxis (PrEP), in HIV, 388–389, 478–479
Pregnancy
  breast stimulation to induce labor in, 209
  diabetes mellitus in, 811
  early loss (miscarriage), 658–659, 1052–1053
  ectopic, 184–185, 318–319, 658, 732, 1052–1053
  fetal hiccups in, 472
  hyperemesis gravidarum in, 496–497
  in-flight emergency, 26–27
  intrauterine growth restriction in, 360
  ovarian cysts in, 732–733
  postpartum “blues,” 266
  postpartum depression, 266–267
  postpartum infections, 332–333
  postpartum thyroiditis, 514, 990–991
  postterm, 811
  prenatal care and testing in, 810–811
  preterm labor in, 818–819, 1053
  prevention of (contraception), 218–219
  pruritis folliculitis of, 370
  recurrent loss, 658–659
  Rh incompatibility in, 880–881
  toxemia of, 806–807
  toxoplasmosis in, 1004–1005
  vaginal bleeding during, 1052–1053
Preleukemia. See Myelodysplastic syndromes
Premature birth (prematurity), neonatal respiratory distress syndrome in, 870–871
Premature ejaculation, 320–321
Premenstrual dysphoric disorder (PMDD), 262, 808–809
Premenstrual syndrome (PMS), 808–809
Prenatal care and testing, 810–811
Preoperative evaluation, of noncardiac surgical patient, 812–813, A-93
PreP. See Preexposure prophylaxis (PrEP)
Prepubescent vulvovaginitis, 1088–1089
Prerenal acute kidney injury, 16–17
Presbycusis, 814–815, 998
Prescription drugs, abuse of, 302–303, 954–955
Presenile dementia. See Alzheimer disease
Preseptal cellulitis. See Periorbital cellulitis
Pressure ulcer, 816–817
Preterm labor, 818–819, 1053
Pretravel consultations, 68–69
Preven, 219
Priapism, 820–821
Prickle cell carcinoma. See Cutaneous squamous cell carcinoma
Primary amenorrhea, 38
Primary angle closure (PAC) glaucoma, 400
Primary angle closure suspect (PACS), 400
Primary atypical pneumonia. See Pneumonia, mycoplasma
Primary biliary cirrhosis, 196–197
Primary closed-angle glaucoma, 400–401
Primary CNS vasculitis, 1060–1061
Primary hyperparathyroidism, 502–503
Primary monosymptomatic nocturnal enuresis (PMNE), 334–335
Primary myelofibrosis (PMF), 686–687
Primary open-angle glaucoma, 402–403
Primary ovarian insufficiency, 644
Primary polycythemia. See Polycythemia vera
Primary progressive multiple sclerosis (PPMS), 674
Primary sclerosing cholangitis, 232
Primary syphilis, 966–967
Probiotics, 209
Proctitis, chlamydia, 184
Progestin-only contraceptives, 218
Prolactin, elevated level of, 380–381, 504–505, 774–775
Prolactinoma, 380–381, 504–505, 774–775
Prolapse
   rectal, 448
   uterine, 1044–1045
   vaginal, 1044–1045
   valvular (mitral), 664–665
Prolymphocytic leukemia, 590
Propionibacterium acnes, 10
Prospalalgia. See Trigeminal neuralgia
Prostate cancer, 822–823
Prostatic hyperplasia, benign (BPH), 824–825
Prostatitis, 826–827
Prosthetic joint infections, 720–721
Protein C deficiency, 828–829, 850, 984
Protein S deficiency, 830–831, 850, 984
Proteinuria, 832–833, A-94
Prothrombin 20210 (mutation), 248, 834–835, 850, 984
Prothrombotic state. See Hypercoagulable states
Protozoal diarrhea, 290–291
Pruritus ani, 40, 836–837
Pruritus folliculitis of pregnancy, 370
Pruritus vulvae, 838–839
Pseudoaneurysm, 50
Pseudofolliculitis, 370
Pseudofolliculitis barbae, 370, 840–841
Pseudogout, 842–843
Pseudogynecomastia, 422
Pseudohyperkalemia, 498
Pseudohypoglycemia, 518, 520–521
Pseudohyponatremia, 524
Pseudomembranous croup. See Tracheitis, bacterial
Pseudomonal cellulitis, 168, 172
Pseudomonal conjunctivitis, 214
Pseudomonal folliculitis, 370–371
Pseudomonal lymphangitis, 610
Pseudomonal meningitis, 636–637
Pseudomonal osteomyelitis, 720
Pseudomonal otitis externa, 724
Pseudomonal parotitis, 746
Pseudomonal prostatitis, 826
Pseudomonal pyelonephritis, 854, 855
Pseudophakia, 876
Pseudo-polyarthrite rhizomélique. See Polymyalgia rheumatica
Pseudorubella. See Roseola
Psoriasis, 844–845
  erythrodermic, 844
  follicular, 370
  guttate, 844
  inverse, 844
  nail disease, 844
  plaque (vulgaris), 844
  pustular, 844
  vaginal, 1056–1057
Psoriatic arthritis, 72, 74–75, 844–845
Psychiatric emergency, in-flight, 26–27
Psychodynamic therapy, 230–231
Psychogenic nonepileptic seizures (PNES), 918–919
“Psychogenic rheumatism.” See Fibromyalgia
Psychosis, 846–847
Psychosis, postpartum, 266, 267
Psychotherapy, 230–231
PTH. See Parathyroid hormone
Phthirus pubis, 752
Ptosis, in Horner syndrome, 486–487
PTS. See Postthrombotic syndrome
PTSD. See Posttraumatic stress disorder
Puberty, precocious, A-92
Pubic lice, 752–753
Puerperal abscess. See Breast abscess
Puerperal mastitis, 130–131, 620–621
Pulmonary arterial hypertension (PAH), 848–849
Pulmonary capillary hemangiomatosis (PCH), 848
Pulmonary edema, 868
  high-altitude, 34–35, 69
  noncardiogenic, 868
Pulmonary embolism (PE), 248–249, 850–851, 984–985
  diagnosis, A-95
  in-flight emergency, 26–27
  treatment, A-96
Pulmonary embolism, deep vein thrombophlebitis and, 248–249, 850
Pulmonary fibrosis, 852–853
  idiopathic, 294–295, 852–853
  nonidiopathic, 852
Pulmonary hypertension
  arterial, 848–849
  cor pulmonale with, 220–221
  scleroderma and, 910–911
  ventricular septal defect and, 1064
Pulmonary veno-occlusive disease, 848
Pure red cell aplasia (PRCA), 748
Purging, 58, 142–143
Pustular psoriasis, 844
PV rubra. See Polycythemia vera
Pyarthrosis. See Septic arthritis
Pyelonephritis, 854–855
Pyloric stenosis, 856–857
Pyoderma. See Impetigo
Pyogenic arthritis. See Septic arthritis
Pyogenic granuloma, 416–417
Pyrophosphate arthropathy. See Pseudogout

Q
Qi gong, 208
QT interval prolongation, 156, 600–601
Quincke edema. See Angioedema

R
RA. See Rheumatoid arthritis
Rabies, 68, 122–123, 858–859
Radiation-induced thyroiditis, 990
Radiculopathy, diabetic, 288
Radiculoplexus neuropathy, 288
Raeder paratrigeminal syndromes, 486
Rape crisis syndrome, 860–861
Rapid cycling, in bipolar II disorder, 120
Rapid (premature) ejaculation, 320–321
Rash, A-97–A-98. See also specific rashes
Raynaud phenomenon, 862–863, 910–911
Razor bumps. See Pseudofolliculitis barbae
Reactive arthritis, 184, 864–865
Reactive gastropathy, 384–385
Reactive hypoglycemia, 520–521
Rectal bleeding, A-99
Rectal prolapse, 448
Recurrent aphthous stomatitis (RAS), 1030
Recurrent benign lymphocytic (Mollaret) meningitis, 638
Recurrent pregnancy loss, 658–659
Recurrent urinary tract infection, 1037
Red eye, A-100
Reducible hernia, 462
Redundant cusp syndrome. See Mitral valve prolapse
Reflex sympathetic dystrophy, 210–211
Reflex syncope, 960–963
Reflux disease
gastroesophageal, 386–387
Barrett esophagus in, 108–109, 386–387
chronic cough in, 188–189
diagnosis and treatment, A-49
dysphagia in, 316–317
infantile colic in, 200
laryngitis in, 578–579
scleroderma and, 910–911
laryngopharyngeal, 578–579
Reflux gastritis, 384–385
Reflux laryngitis, 578–579
Rehydration, oral, 250–251
Reiki, 208
Reiter syndrome, 184, 864–865
Relapsing-remitting multiple sclerosis (RRMS), 674
Relative Energy Deficiency in Sport (RED-S), 362–363
Relaxation training, 208
Renal calculi
  with Crohn disease, 232
  hematuria with, 442–443
  hydronephrosis with, 492–493
Renal failure, acute (acute kidney injury), 16–17
Renal malignancy, Wilms tumor, 1092–1093
Renal tubular acidosis (RTA), 866–867
Replacement atelectasis, 86–87
Reptile bites, 122–123
Resistant hypertension, 512–513
Resorptive (obstructive) atelectasis, 86–87
Respiratory distress syndrome
  acute, 86–87, 868–869
  neonatal, 870–871
Respiratory syncytial virus (RSV) infection, 872–873
  acute bronchitis in, 140
  bronchiolitis in, 138–139, 872–873
  croup in, 234
  pneumonia in, 872
Restless legs syndrome, 874–875
Restricting type, of anorexia nervosa, 58
Restrictive cardiomyopathy, 156–157
Retarded (delayed) ejaculation, 320–321
Retinal detachment, 876–877
Retinal migraine, 430
Retinitis
  CMV, 478
  herpes, 464
Retinochoroiditis, 1048–1049
Retinopathy, diabetic, 878–879
Retractile cryptorchidism, 236–237
Retrobulbar optic neuritis. See Optic neuritis
Retrograde ejaculation, 320–321
Retropatellar pain syndrome. See Patellofemoral pain syndrome
Retroviral syndrome, acute, 478
Reversible cognitive impairment, 656
Rhabdomyolysis, 882–883
Rhabdomyosarcoma, 124–125, 884–885, 1054
Rh alloimmunization. See Rh incompatibility
Rhegmatogenous retinal detachment (RRD), 876–877
Rheumatic fever, 660, 662–663, 768–769, 886–887
Rheumatic heart disease, 64–65, 660, 662–663, 886–887
Rheumatoid arthritis (RA), 76–77
Rheumatoid arthritis (RA), juvenile, 72–73
Rheumatoid vasculitis, 1060–1061
Rh immunization. See Rh incompatibility
Rh incompatibility, 880–881
Rhinitis
allergic, 888–889
infectious, 888
nonallergic, 888
Rhinosinusitis, 928–929
Rh isoimmunization. See Rh incompatibility
Rh sensitization. See Rh incompatibility
Riboflavin, 209, 1077
Richter hernia, 462
Rickets, 1074–1077, A-114
Rickettsia, 890, 1028
Riedel thyroiditis, 990–991
Right middle lobe syndrome, 86
Ringworm, 992–993
Ringworm of nail. See Onychomycosis
Rocky Mountain spotted fever, 890–891
Rodent bites, 122–123
Rolandic epilepsy, benign, 916–917
Rosacea (acne rosacea), 8–9, 370
Rosacea-like dermatitis. See Perioral dermatitis
Roseola, 892–893
Rotator cuff impingement syndrome, 894–895, 926–927
Rotavirus vaccine, 68
Rounded atelectasis, 86–87
RRD. See Rhegmatogenous retinal detachment
RSV. See Respiratory syncytial virus
RTA. See Renal tubular acidosis
Rubella, 626–627
Rubeola (measles), 624–625
Rule of 9s, in burns, 146
Rule of Threes, for colic, 200
Runner’s knee, 750–751
Ruptured ovarian cyst, 732–733
Ruptured uterus, 1052

S
SAD. See Seasonal affective disorder
Safe sex practices, 388
Saffron, 208
SAH. See Subarachnoid hemorrhage
St. Anthony’s fire. See Erysipelas
St. John’s wort, 209, 292
St. Louis encephalitis virus, 638
Salicylate poisoning, acute, treatment of, A-101
Salivary gland calculi, 746, 896–897
Salmonella enterica, 898
Salmonella paratyphi, 1026
Salmonella typhi, 899, 1026
Salpingitis, 754–755
Salt and water loss dehydration, 250–251
Sampson theory, of endometriosis, 330
Sarcoidosis, 900–901
Sarcoid vasculitis, 1060–1061
Sarcoma
  ovarian, 730–731
  rhabdomyosarcoma, 884–885, 1054
  uterine, 328–329
  vaginal, 1054–1055
  vulvar, 1082
Sarcoptes scabiei var. hominis, 902
Sarcoptic mange. See Scabies
SBE. See Subacute bacterial endocarditis
SBP. See Spontaneous bacterial peritonitis
Scabies, 80–81, 902–903
Scalenus anticus syndrome. See Thoracic outlet syndrome
Scapulohumeral periarthritis. See Adhesive capsulitis
Scarlatina. See Scarlet fever
Scarlet fever, 904–905
Scarring alopecia, 32–33
SCC. See Squamous cell carcinoma
SCH. See Subconjunctival hemorrhage
Schaumann disease. See Sarcoidosis
Schistosomes, 370
Schizoaffective disorder, 846
Schizophrenia, 231, 846–847, 906–907
Schwannoma, 694
SCI. See Spinal cord injury
SCIWORA syndrome, 176
SCLC. See Small cell lung cancer
Scleritis, 214, 908–909
Scleroderma, 910–911
Sclerosing lymphangitis of penis, 610
Scorpion stings, 80–81
Scrub typhus, 1028–1029
Scuba diving, 26, 69
Scurvy, 1077
Sea sickness. See Motion sickness
Seasonal affective disorder (SAD), 912–913
Seasonal allergic rhinitis, 888–889
Seborrheic dermatitis, 278–279
Seborrheic keratitis, 570–571
Seborrheic wart. See Seborrheic keratosis
Secondary amenorrhea, 38
Secondary hyperparathyroidism, 502–503
Secondary hypertension, 510, 512–513
Secondary progressive multiple sclerosis (SPMS), 674
Secondary syphilis, 966–967
Second-impact syndrome, 129, 803
Secretory diarrhea, 292–293
Secretory otitis media. See Otitis media
Seizure disorders, 918–919
absence, 914–915
febrile seizures, 918, 920–921
focal, 916–917
in-flight emergency, 26–27
medical marijuana for, 630
new onset seizures, A-102
status epilepticus, 918–921
Self-neglect, elder, 322–323
Semen analysis, 546
Seminomatous germ cell tumors, 974–975
Senile dementia
  of Alzheimer type (See Alzheimer disease)
  due to hardening of the arteries (See Vascular dementia)
Senile macular degeneration. See Age-related macular degeneration
Senile rheumatic disease. See Polymyalgia rheumatica
Senile wart. See Seborrheic keratosis
Senna, 209
Sensorineural hearing loss (SNHL), 434–435, 814–815, 998–999
Sepsis, MRSA and, 654–655
Septal defect
  atrial, 90–91
  ventricular, 660, 1064–1065
Septic abortion, 658
Septic arthritis, 78–79
Septic thrombophlebitis, 654
Septic (suppurative) thrombophlebitis, 958–959
Sequestration crisis, 48
Serotonin syndrome, 261, 922–923
Serous otitis media. See Otitis media
Serous retinal detachment, 876–877
Sex cord stromal tumors, ovarian, 730–731
Sexual assault, 860–861
Sexual behaviors, normative, 114–115
Sexual contact, 860
Sexual dysfunction in men
  ejaculatory disorders, 320–321
  erectile dysfunction, 344–345
  priapism, 820–821
  testosterone deficiency, 978–979
Sexual dysfunction in women, 924–925
  genito-pelvic pain/penetration disorder, 390–391, 924–925
  vaginismus, 390–391, 924–925
vulvodynia, 838–839, 1084–1085
Sexually transmitted infections (STIs). See also specific types
gay men and, 388–389
lesbians and, 584
rape and, 860–861
Sexual orientation, 388–389, 584–585
Sexual trauma, military, 860
Sexual violence, 860–861
Shaken baby syndrome, 200, 201
Shaving bumps. See Pseudofolliculitis barbae
Shellfish allergy, 372–373
Shift work disorder (SWD), 934–935
Shigella
  bacterial diarrhea, 290–291
  food poisoning, 374–375
  prepubescent vulvovaginitis, 1088–1089
  reactive arthritis (Reiter syndrome), 864–865
Shingles (herpes zoster), 180–181, 464–465, 470–471
Shingles (herpes zoster) vaccine, 68, 180, 464–465, 470–471
Shingrix, 180, 464–465, 470–471
Shin splints, 628–629
Shock lung. See Acute respiratory distress syndrome
Short bowel syndrome, 292
Shortness of breath, in-flight, 26
Shoulder, frozen (adhesive capsulitis), 20–21, 926–927
Shoulder pain, 926–927
  in adhesive capsulitis, 20–21, 926–927
  in rotator cuff impingement syndrome, 894–895, 926–927
  treatment, A-103
Shoulder sprain, 944
Sialadenitis, 896–897
Sialolithiasis, 746, 896–897
Sickle cell anemia, 48–49
  acute, evaluation and management, A-104–A-105
  types of crises in, 48
Sickle cell disease. See Sickle cell anemia
Sideline evaluation, concussion, A-27
Silent thyroiditis, 990–991
Singultus. See Hiccups
Sinusitis, 928–929
Sinus venosus defect, 90–91
Situational syncope, 960, 962–963
Sixth disease. See Roseola
Sjögren syndrome, 930–931
  parotitis in, 746–747
Skin cancer
  actinic keratosis and, 568–569
  atypical mole (dysplastic nevus) syndrome and, 96–97, 632–633
  basal cell carcinoma, 110–111
  melanoma, 96–97, 632–633, 1054–1055, 1082
  squamous cell, 946–947
Skin infections. See also specific types
  MRSA, 654–655
Skylla, 219
SLE. See Systemic lupus erythematosus
Sleep apnea, obstructive, 932–933
  pediatric, 114–115
Sleep disorders/problems
  Alzheimer disease-related, 37
  circadian rhythm, 554–555, 934–935
  geriatric depression and, 264
  insomnia, 554–555
    in Alzheimer disease, 37
    chronic, 554–555
    and in-flight emergency, 26
    transient/intermittent, 554–555
  jet lag, 69, 554–555
  menopause-related, 644
  narcolepsy, 688–689
  obstructive apnea, 114–115, 932–933
  pediatric, 114–115
  periodic limb movement disorder, 760–761
  in posttraumatic stress disorder, 804–805
  restless legs syndrome, 874–875
  shift work disorder, 934–935
  unrefreshing sleep, 680
Sleep myoclonus. See Periodic limb movement disorder
Sleep paralysis, 688–689
Sleepwalking, in children, 114
Sliding hernia, 462
Slow fever. See Typhoid fever
Small cell carcinoma
bladder, 124–125
vulvar, 1082
Small cell lung cancer (SCLC), 602–603
Small-vessel vasculitis, 1060–1061
Smell and taste disorders, 936–937
Smoke inhalation, 146–147
Smokeless tobacco, 1000
Smoking (nicotine addiction), 388, 584, 700–701, 954–955, 1000–1001
Smoking cessation, 700–701, 1000–1001
Snake bites, 122–123
Snakeroot, 209
Sodium
   hypernatremia, 500–501, A-63
   hyponatremia, 524–525, A-69
      SIADH and, 524–525, 964–965
tonicity and, 524
Soft corn (heloma molle), 224–225
Soiling. See Encopresis
Solar keratosis. See Actinic keratosis
Solar urticaria, 1042–1043
Somatic pain, 194
Somatic symptom (somatization) disorder (SSD), 938–939
Somatoform disorders, 231
Somatotroph adenoma, 774–775
Sore throat. See Pharyngitis
Space sickness. See Motion sickness
Spastic colon. See Irritable bowel syndrome
Spells. See Seizure disorders
Spermicides, 219
Spider bites, 80–81
Spider veins, 1058–1059, 1062
Spigelian hernia, 462
Spinal cord injury
   cervical, 176–177, A-19–A-20
   without radiologic abnormality (SCIWORA), 176
Spinal manipulative therapy, 208
Spinal osteoarthritis, 718
Spinal stenosis, 940–941
Spindle cell rhabdomyosarcoma, 884–885
Spiritual practices, 208
Spleen, overactive, 508–509
Splenomegalic polycythemia. See Polycythemia vera
Splenomegaly, 508–509
Spondyloarthritis, 74
Spondyloarthropathy, axial inflammatory, 56
Spondylosis, 940
Sponge, contraceptive, 218–219
Spontaneous abortion (miscarriage), 658–659, 1052–1053
Spontaneous acute urticaria, 1042
Spontaneous bacterial peritonitis (SBP), 764–765
Spontaneous chronic urticaria, 1042
Spontaneous (fasting) hypoglycemia, 518, 520
Sports hernia, 462
Sports-related injuries, 552–553
Spotted fever rickettsioses (SFRs), 890–891
Spousal abuse. See Domestic violence
Sprains, 944–945
  ankle, 942–945
  cervical, 176–177
  knee, 944
  lumbar (low back pain), 102–103
  shoulder, 944
Squamous cell carcinoma (SCC)
  bladder, 124–125
  cutaneous, 946–947
  lung, 602–603
  vaginal, 1054–1055
  vulvar, 1082
SSD. See Somatic symptom (somatization) disorder
Stable angina, 226–227
Staghorn calculi, 1040
Staphylococcus aureus infections
  asymptomatic bacteriuria, 104
  breast, 130–131, 135, 620–621
  cellulitis, 168–173
  epididymitis, 338
  folliculitis, 370–371, 536
  foodborne, 374–375
  furunculosis, 378–379
  impetigo, 536–537
  infective endocarditis, 326
lymphangitis, 610
mastoiditis, 622–623
osteomyelitis, 720–721
otitis externa, 724–725
paronychia, 744–745
parotitis, 746
pneumonia, 780
postpartum, 332
prepubescent vulvovaginitis, 1089
prostatitis, 826
pyelonephritis, 854, 855
septic arthritis, 78
sinusitis, 928
skin, methicillin-resistant, 654–655
tracheitis, 1006
Staphylococcus infections. See also Staphylococcus aureus infection
  conjunctivitis, 214, 215
  epididymitis, 338
  glomerulonephritis after, 406–407
  hordeolum (stye), 484
  infective endocarditis, 326–327
  peritonitis, 764–765
  pyelonephritis, 854
Stasis dermatitis, 280–281, 532
Status epilepticus, 918–919
Status epilepticus, febrile, 920–921
Status migrainosus, 430–431
Steatohepatitis, nonalcoholic, 196, 702–703
Stein–Leventhal syndrome. See Polycystic ovary syndrome
STEMI (ST-segment elevation myocardial infarction), 14–15, 226–227
Sterilization, 218–219
Steroid (anabolic steroid) abuse, 954
Stevens–Johnson syndrome, 240–241, 348
Stewardess disease. See Perioral dermatitis
Stiffness, A-23
Still disease, 72–73
Stimulant abuse, 302–303, 954–955
Stings, arthropod, 80–81
STIs. See Sexually transmitted infections
Stomatitis
  aphthous (aphthous ulcer), 1030–1031
Vincent, 398–399, 1070–1071
Stones. See Calculi
Strains, 944–945
  cervical, 176–177
  lumbar (low back pain), 102–103
Strangulated hemorrhoid, 449
Strangulated hernia, 462–463
Strep throat. See Pharyngitis
Streptococcus infections
  acute bronchitis, 140
  asymptomatic bacteriuria, 104
  breast, 130
  cellulitis, 168–173
  conjunctivitis, 214, 215
  dental infections, 258
  erysipelas, 346–347
  folliculitis, 370
  glomerulonephritis after, 404, 406–407, 536, 537
  group A β-hemolytic, 768–769, 886–887, 904–905, 1002
  group B, 636–637, 811
  HIV-related, 479
  impetigo, 536–537
  infective endocarditis, 326–327
  lymphangitis, 610
  mastitis, 620
  mastoiditis, 622–623
  meningitis, 636–637
  osteomyelitis, 720
  otitis externa, 724–725
  otitis media, 726, 728
  PANDAS, 1002
  paronychia, 744
  parotitis, 746
  peritonitis, 764–765
  pharyngitis, 768–769, 904–905
  pneumonia, 780–781
  postpartum, 332
  prepubescent vulvovaginitis, 1088–1089
  prostatitis, 826
  rheumatic fever, 660, 662–663, 768–769, 886–887
  scarlet fever, 904–905
septic arthritis, 78
sinusitis, 928
tracheitis, 1006
Streptococcus mutans, 258
Stress cardiomyopathies, 156, 1012–1013
Stress disorder
  acute, sexual violence and, 860–861
  posttraumatic, 630, 804–805, 846, 860–861
Stress fracture, 948–949
Stress headache. See Tension headache
Stress incontinence, 540–543
Strictures, peptic, 386–387
Stroke
  acute, 950–951
  atrial fibrillation and, 88–89
  hemorrhagic, 950–951
  in-flight emergency, 26–27
  ischemic, 950–951
  sickle cell anemia and, 48–49
  transient ischemic attack and, 950–951, 1010–1011, A-110
Structural hair disorders, 32–33
Struvite stones, 1040–1041
ST-segment elevation myocardial infarction (STEMI), 14–15, 226–227
Stucco keratosis, 570
Stuttering priapism, 820–821
Stye (hordeolum), 484–485
Subacromial bursitis, 926
Subacute bacterial endocarditis (SBE), 326–327
Subacute/de Quervain thyroiditis, 514, 990–991
Subacute granulomatous thyroiditis, 990–991
Subacute sclerosing panencephalitis, 625
Subarachnoid hemorrhage (SAH), 950
Subareolar abscess. See Breast abscess
Subclinical hyperthyroidism, 514
Subconjunctival hemorrhage (SCH), 952–953
Subdural hematoma, 128, 129
Subjective tinnitus, 998–999
Submandibular calculi, 896–897
Submassive pulmonary embolism, 850
Submersion injury (nonfatal drowning), 704–705
Subretinal neovascularization. See Age-related macular degeneration
Substance-induced psychosis, 846
Substance/medication-induced depressive disorder, 262
Substance/medication-induced neurocognitive disorder, 254
Substance use disorders, 954–955. See also Drug (substance) abuse
Subsyndromal delirium, 252
Subungual melanoma, 632
Subungual SCC, 946
SUDD. See Symptomatic uncomplicated diverticular disease
Sudden cardiac death, 600
Suffocation, 552–553
Suicide, 552–553, 956–957
  bipolar I disorder and, 119
  bipolar II disorder and, 121
  borderline personality disorder and, 126–127
  depression and, 260–265, 956–957
  evaluating risk for, A-106
  geriatric, 264–265
  LGBT persons and, 389
  psychosis and, 846–847
  transgender persons and, 1008
Sundowner syndrome, 255
Superficial spreading melanoma, 632
Superficial thrombophlebitis, 958–959
Suppurative (septic) arthritis, 78–79
Suppurative (septic) thrombophlebitis, 958–959
Suppurative thyroiditis, 514
Surfactant deficiency. See Neonatal respiratory distress syndrome
Surgery, preoperative evaluation of noncardiac patient for, 812–813, A-93
Surgical menopause, 644
Suspected nonaccidental trauma. See Child abuse
Swallowing. See Dysphagia
SWD. See Shift work disorder
Sweet syndrome (acute febrile neutrophilic dermatosis), 240–241
Swimmer’s ear, 724–725
Swimmer’s itch (schistosomes), 370
Symmetric polyarthritis, 74, 76
Symmetric polyneuropathy, 288–289
Sympathetically maintained pain. See Complex regional pain syndrome
Symptomatic diverticulosis, 296–297
Symptomatic uncomplicated diverticular disease (SUDD), 296–297
Syncope, 960–961, A-107
aortic valvular stenosis and, 64–65
atrial fibrillation/flutter and, 88
carotid sinus hypersensitivity and, 158–159, 960–963
in-flight emergency, 26–27
long QT syndrome and, 600–601
reflex (vasovagal), 960–963
transient stress cardiomyopathy and, 1012
Syndesmotic ankle sprains, 942–943
Syndrome of inappropriate antidiuretic hormone (SIADH), 524–525, 964–965
Syphilis, 966–967
  alopecia in, 32, 33
gay men and, 388
  in HIV-infected persons, 478
lesbians and, 584
  neurosyphilis, 966–967
rape and, 861
Syphilis-associated aortitis, 1060–1061
Systemic exertion intolerance syndrome, 680–681
Systemic lupus erythematosus (SLE), 604–605
  mastitis in, 620
  nephritis in, 404–405, 406, 560, 561, 606–607
  nephropathy in, 692
  vasculitis in, 1060–1061
Systemic sclerosis. See Scleroderma
Systolic click-murmur syndrome. See Mitral valve prolapse

T
Tai chi, 208
Takayasu arteritis, 1060–1061
Takotsubo cardiomyopathy. See Transient stress cardiomyopathy
Tardive dyskinesia, 846–847
Tarsal tunnel syndrome, 968–969
Taste disorders, 936–937
TB. See Tuberculosis
TBI. See Traumatic brain injury
Tdap vaccine, 68, 766
Teardrop fractures, hyperextension, 177
Telangiectasia, 8–9, 1058–1059, 1062
Telogen effluvium, 32–33, 970–971
Temperature, body
  fever
in first 90 days of life, A-46
  seizures with, 918, 920–921
  of unknown origin (FUO), 364–365, A-47
  hyperthermia, 392, 440–441
  hypothermia, 392, 528–529
Temper tantrums, 114–115
Temporal (giant cell) arteritis, 70–71, 1060–1061
Temporomandibular joint disorder (TMD), 972–973
TEN. See Toxic epidermal necrolysis
Tendinopathy, 1020
  biceps, 926–927
  elbow, 336–337
  patellar, 572–573
Tennis elbow, 336–337
Tenosynovitis
  de Quervain, 246–247
  digital stenosing, 1018–1019
Tension headache, 432–433
Tension pneumothorax, in-flight emergency, 26–27
Tertiary hyperparathyroidism, 502–503
Tertiary syphilis, 966–967
Testes, undescended, 236–237, 974
Testicular malignancies, 974–975
Testicular torsion, 976–977
Testosterone deficiency, 978–979
Tetanus, diphtheria, and pertussis vaccine, 68, 766
Thalassemia, 980–981
Thoracic outlet syndrome (TOS), 982–983
Threatened abortion, 658, 1052–1053
3-day fever. See Roseola
3-day measles. See German measles
Thrombocytopenia, A-108
  heparin-induced, 452–453
  immune, 534–535
  myelodysplastic syndromes, 684–685
Thromboembolic pulmonary hypertension, chronic, 848
Thromboembolism, venous, 248–249, 850–851, 984–985. See also Deep vein thrombophlebitis;
  Pulmonary embolism
  in-flight emergency, 26–27
Thrombophilia, 984–985
Thrombophlebitis
    deep vein (See Deep vein thrombophlebitis)
    septic, MRSA and, 654
    superficial, 958–959
    varicose veins with, 1058–1059
Thrombosed hemorrhoids, 40, 448–449
Thrombosis, deep vein. See Deep vein thrombophlebitis
Thrombotic thrombocytopenic purpura (TTP), 986–987
Thrush, 150–151
Thumb sucking, 114–115
Thyroid dysfunction. See also specific disorders
goiter, 418–419, 514–515
    granuloma annulare in, 414
Graves disease, 418–419, 514–515

Trisomy 21. See Down syndrome
Trochanteric bursitis, 1020–1021
Troisier–Hanot–Chauffard syndrome. See Hemochromatosis
Trousseau syndrome, 958
True aneurysm, 50
TTM. See Trichotillomania
TTP. See Thrombotic thrombocytopenic purpura
Tubal ectopic pregnancy, 318–319
Tubal ligation, 219
Tuberculosis, 1022–1023
epididymitis in, 338
extensively drug-resistant, 1023
HIV-associated, 478–479, 1022–1025
latent, 1022, 1024–1025
multidrug-resistant, 1023
osteomyelitis in, 720
Tubo-ovarian abscess, 754–755
Tubular necrosis, acute, 16
Tubular proteinuria, 832–833
Tubulointerstitial nephritis with uveitis (TINU), 560, 561
Turcot syndrome, 206
Tyloma. See Calluses
Tyloma (callus), 224–225
Typhoid fever, 68, 898, 1026–1027
Typhus abdominalis. See Typhoid fever
Typhus fevers, 1028–1029
Typical angina, 226

U
Ulcer(s)
aphthous, 1030–1031
corneal, 214, 222–223
genital, A-50
lower extremity (leg), 1062–1063
Marjolin, 946
peptic, 756–757
pressure, 816–817
venous insufficiency, 1062–1063
Ulcerative colitis, 1032–1033
chronic diarrhea in, 292–293
colon cancer risk in, 204, 205
Crohn disease versus, 232
Ulcerative gingivitis, acute necrotizing, 398–399, 1070–1071
Ulcerogenic islet cell tumor. See Zollinger–Ellison syndrome
Ulipristal acetate, 219
Ultrasound, breast, 304
Umbilical hernia, 462–463
Uncomplicated urinary tract infection, 1038–1037
Uncontrolled hypertension, 512–513
Undescended testes, 236–237, 974
Ungulate bites, 122–123
Unrefreshing sleep, 680
Unstable angina, 12–13, 26, 226–227
Upper abdominal pain, A-4
Upper airway cough syndrome (UACS), 188
Upper gastrointestinal bleeding, A-54
Urate nephropathy, 561
Uremia, A-17
Ureteric stones, 1040–1041
Urethritis, 1034–1035
chlamydial, 184–185, 1034–1035
gonococcal, 410–411, 1034–1035
reactive arthritis, 864–865
trichomonal, 1014–1015, 1034–1035
Urethro-oculosynovial syndrome. See Reactive arthritis
Urge incontinence, 540–543
Urgency frequency syndrome. See Interstitial cystitis
Uric acid stones, 1040–1041
Urinary bladder
  cancer of, 124–125
  pain or discomfort (interstitial cystitis), 558–559
  stones in, 1040–1041
Urinary incontinence
adult female, 540–541
adult male, 542–543
benign prostatic hyperplasia and, 824–825
enuresis, 114–115, 334–335
geriatric, 392
Urinary tract infection (UTI)
  acute upper (pyelonephritis), 854–855
  in elderly, 392
in females, 1036–1037
hematuria in, 442–443
hydronephrosis with, 492–493
in males, 1038–1039
Urinary tract obstruction (UTO), hydronephrosis with, 492–493
Urination
enuresis, 334–335
daytime, 334–335
nocturnal, 114–115, 334–335
primary, 334
secondary, 334
excessive (polyuria), 542
Urine
bacteria in (asymptomatic bacteriuria), 104–105
blood in (hematuria), 442–443, A-55
calcium in (hypercalciuria), 1040, 1041
protein in, 832–833, A-94
Urolithiasis, 1040–1041
Uropathy, obstructive, 492
Urticaria, 52, 1042–1043
Urticarial drug reactions, 240–241
Urticarial vasculitis, hypocomplementemic, 1060–1061
Usual interstitial pneumonia, 852–853
Uterine bleeding, abnormal (dysfunctional), 2–3, 646–647
Uterine cancer. See Endometrial cancer
Uterine myomas, 1046–1047
Uterine prolapse, 1044–1045
Uterine rupture, 1052
Uterine sarcoma, 328–329
UTI. See Urinary tract infection
Uveitis, 214, 1048–1049
herpes, 464–465, 468
tubulointerstitial nephritis with, 560, 561
V
Vaccines. See also specific vaccines
for HIV patients, 479
for travel, 68
Vaginal adenosis, 1050–1051
Vaginal atrophy, 644–645, 1086–1087
Vaginal bleeding
abnormal, A-113
during pregnancy, 1052–1053
Vaginal candidiasis, 150–151, 1056–1057, 1089
Vaginal contraceptive ring, 218
Vaginal intraepithelial neoplasia (VAIN), 1054–1055
Vaginal malignancy, 1054–1055
Vaginal prolapse, 1044–1045
Vaginismus, 390–391, 924–925, 1084–1085
Vaginitis, 1056–1057. See also Vulvovaginitis
desquamative inflammatory, 1056
prepubescent, 1088–1089
trichomonal, 1014–1015
Vaginosis, 584, 861, 1056–1057
VAIN. See Vaginal intraepithelial neoplasia
VAP. See Ventilator-associated pneumonia
Vaping (vaporizing device), 954, 1000–1001
Vaquez disease. See Polycythemia vera
Vaquez–Osler disease. See Polycythemia vera
Varicella zoster, 180–181, 464–465, 638. See also Herpes zoster (shingles)
Varicella zoster vaccine, 68, 180
Varices
esophageal, 196–197, 352–353, 800–801
gastric, 800–801
Varicose eczema. See Stasis dermatitis
Varicose veins, 1058–1059, 1062
Varivax (varicella zoster vaccine), 180
Vasa previa, 1052–1053
Vascular cognitive disorder. See Vascular dementia
Vascular dementia, 254–257
Vasculitis, 1060–1061
Henoch-Schönlein purpura, 404–405, 406, 450–451, 1060–1061
hypersensitivity, 240–241, 1060–1061
Kawasaki syndrome, 564–565, 1060–1061
polyarteritis nodosa, 786–787, 1060–1061
temporal arteritis, 70–71, 1060–1061
Vasectomy, 218–219
Vasomotor symptoms, in menopause, 644
Vaso-occlusive crisis, 48
Vasovagal syncope, 960–963
in-flight emergency, 26–27
Veins
spider, 1058–1059, 1062
varicose, 1058–1059, 1062
Venous dermatitis. See Stasis dermatitis
Venous insufficiency, stasis dermatitis with, 280–281
Venous insufficiency ulcers, 1062–1063
Venous thromboembolism (VTE), 248–249, 850–851, 984–985. See also Deep vein
thrombophlebitis; Pulmonary embolism
in-flight emergency, 26–27
Ventilator-associated pneumonia (VAP), 780–781
Ventral hernia, 462–463
Ventricular septal defect (VSD), 660, 1064–1065
Ventricular tachycardia, catecholaminergic polymorphic, 156
Verneuil disease. See Hidradenitis suppurativa
Verrucae. See Warts
Verruca seborrhoica. See Seborrheic keratosis
Verruca senilis. See Seborrheic keratosis
Verrucous carcinoma
  cutaneous, 946
  vulvar, 1082
Vertebral artery dissection, 176
Vertebral osteomyelitis, 720–721
Vertigo, 1066–1067, A-41
  benign paroxysmal positional, 574–575, 1068–1069
  eustachian tube dysfunction and, 356
  hearing loss with (Ménière disease), 634–635, 1066–1067
  labyrinthitis and, 574–575, 1066–1067
  physiologic (See Motion sickness)
Vesical calculosis, 1040–1041
Vesicoureteral reflux (VUR), hydronephrosis with, 492–493
Vesicular palmoplantar eczema. See Dyshidrosis
Vestibular neuritis. See Labyrinthitis
Vestibular neuritis/neuronitis, 574
Vestibular neuronitis. See Labyrinthitis
Vestibular/vertiginous migraine, 574, 1066–1067
Vestibulodynia, 1084–1085
Vibratory urticaria, 1042–1043
Vibrio cholerae, 374–375
Vibrio parahaemolyticus, 374–375
Vibrio vulnificus, 374–375
Video gaming disorder, 382–383
Viking’s disease. See Dupuytren contracture
VIN. See Vulvar intraepithelial neoplasia
Vincent disease (stomatitis), 398–399, 1070–1071
Violence, 552–553
  domestic, 298–299, 389, 482, 552–553, 584–585, 810
  sexual, 860–861
Viral croup. See Croup
Viral diarrhea
  acute, 290–291
  chronic, 292–293
Viral meningitis, 638–639
Viral parotitis, 746–747
Viral/retroviral-associated vasculitis, 1060
Viral sinusitis, 928
Virchow triad, 984
Visceral pain, 194
Vision
  age-related macular degeneration and, 614–615
  cataract and, 164–165
  chemical burns and, 710–711
  diabetic retinopathy and, 878–879
  glaucoma and, 400–403
  measles and, 625
  multiple sclerosis and, 674–675, 714–715
  myasthenia gravis and, 682–683
  optic neuritis and, 674–675, 714–715
  retinal detachment and, 876–877
  scleritis and, 908–909
  subconjunctival hemorrhage and, 952–953
  toxoplasmosis and, 1004–1005
  uveitis and, 1048–1049
Vitamin(s)
  deficiency, 1076–1077
  toxicity, 1076, 1077
Vitamin A, 209
Vitamin A deficiency, 1076–1077
Vitamin B1 deficiency, 1076
Vitamin B2 (riboflavin), 209
Vitamin B2 deficiency, 1077
Vitamin B3 deficiency, 1077
Vitamin B5 deficiency, 1077
Vitamin B<sub>6</sub> deficiency, 1077
Vitamin B<sub>12</sub> deficiency, 1072–1073, 1076–1077
Vitamin C deficiency, 1077
Vitamin D, 209
Vitamin D deficiency, 1074–1077, A-114
Vitamin E deficiency, 1076–1077
Vitamin K deficiency, 1076–1077
Vitiligo, 1078–1079
Vitreous detachment, 876
Vitreous hemorrhage, 876–877
Vomiting
  - blood in (hematemesis), A-54
  - chemotherapy-induced, medical marijuana for, 630
  - cyclic syndrome, 242–243
  - in eating disorders, 58, 142–143
  - in hyperemesis gravidarum, 496–497
  - in motion sickness, 670–671
  - in pyloric stenosis, 856–857
Von Recklinghausen disease. See Neurofibromatosis type 1
Von Willebrand disease (vWD), 1080–1081
VSD. See Ventricular septal defect
VTE. See Venous thromboembolism
Vulvar intraepithelial neoplasia (VIN), 1082–1083
Vulvar malignancy, 1082–1083
Vulvar pruritus, 838–839
Vulvar/vaginal atrophy, 644–645, 1086–1087
Vulvitis. See also Vulvovaginitis
  - prepubescent, 1088–1089
Vulvodynia, 838–839, 1084–1085
Vulvovaginal candidiasis, 150–151, 1056–1057, 1089
Vulvovaginitis
  - estrogen-deficient, 1086–1087
  - prepubescent, 1088–1089
vWD. See von Willebrand disease

W
Waldenstrom disease. See Polycythemia vera
Walking pneumonia, 782–783
Warts, 1090–1091
  - genital (condylomata acuminata), 4–5, 212–213, 1090–1091
  - seborrheic (See Seborrheic keratosis)
senile (See Seborrheic keratosis)
Water loss dehydration, 250–251
Wegener granulomatosis, 294–295
Weight loss
  in anorexia nervosa, 58–59
  in elderly, 392
Weight loss, unintentional, A-115
Weir Mitchell causalgia. See Complex regional pain syndrome
Werlhof disease. See Immune thrombocytopenia
Wernicke encephalopathy, 1076
West Nile virus, 638
Wet beriberi, 1076
Wet lung. See Acute respiratory distress syndrome
Wheals. See Urticaria
Wheat allergy, 372–373
Whiplash injuries, 176–177
Whipple disease, 292–293
White-coat hypertension, 510, 512–513
Whooping cough. See Pertussis
Willis–Ekbom disease. See Restless legs syndrome
Wilms tumor, 1092–1093
Wilson disease, 196–197
Winter blues, 912
Withdrawal, alcohol, 30–31, 955, A-8
  delirium in, 252–253
  treatment, 30–31
Withdrawal, drug, 955
Withdrawal method, 219
Women who have sex with women (WSW), 584–585
Worms, pinworms, 772–773
Wormwood, 209
WSW. See Women who have sex with women

X
Xeroderma pigmentosum, 632
Xerophthalmia, in Sjögren syndrome, 930–931
Xerostomia, in Sjögren syndrome, 930–931
Xulane, 218

Y
Yeast infection. See Candidiasis
Yellow fever vaccine, 68
Yersinia, 864–865
Yersinia enterocolitica, 374–375
Yoga, 208–209
Yohimbe, 209
Youth
  homelessness, 482
  LGBT, 388–389, 584–585, 1008–1009
Yuzpe regimen, 219

Z
Zeisian stye. See Hordeolum
Zeitgebers, 934
Zollinger–Ellison syndrome, 1094–1095
Zoon balanitis, 106–107
Zostavax, 464–465, 470–471
Zoster-associated pain, 470–471
